THE
PHOTOGRAPHIC NEWS:

A WEEKLY RECORD

OF THE

PROGRESS OF PHOTOGRAPHY.

VOLUME XV.

EDITED BY G. WHARTON SIMPSON, M.A., F.S.A.

Nulla recordanti lux est ingrata.—MARTIAL.

LONDON:

PRINTED AND PUBLISHED BY PIPER AND CARTER,
15 & 16, GOUGH SQUARE, FLEET STREET, E.C.

1871.

LONDON :
PIPER AND CARTER, PRINTERS, GOUGH SQUARE.

THE preface to a volume is generally the last duty an author undertakes in relation to his work before sending it into the world, and is intended to explain, or qualify, or enforce, or justify some portion of the contents of the work, or, at least, to give its *raison d'être*. Our duty in writing these after-words has none of these purposes. The work which has reached the reader in fifty-two instalments is now before him in its integral form. It has been read and pondered, examined and tested, approved or condemned, week by week for twelve months. Such right to existence as the work possesses has already been demonstrated. Its immediate good or evil has been effected, and explanation or qualification would effect little now. "What is writ is writ:" and a preface will avail us nothing if the work itself be wanting. Further, in these lines we are not in the position of the author who prefaces his own work. The Volume completed is only in a small sense ours; it contains the experience, the judgment, the suggestion, the dicta of the master-spirits associated with photography throughout the world. It is in this fact which we feel bold, and present the Fifteenth Volume of the PHOTOGRAPHIC NEWS to the photographic world with no misgivings: without plea, protest, or qualification. We have been so freely and so ably assisted by contributors and correspondents in laying before our readers detail and results of experiment; suggestion and teaching of practice; discovery, modification, and improvement in every branch of the art, and every phase of every branch, that it would be an ungrateful affectation of humility if we underrated the value of the work. Not only at home have we received such assistance, but through correspondents, regular and occasional, throughout Europe, India, Australia, and America, we have constant contributions to the common fund of photographic intelligence upon which progress depends. From America, not only are we kept supplied with the earliest and most practical information by our esteemed *collaborateur*, Mr. E. L. Wilson, but, through his courtesy in forwarding us advance sheets, we have the practical access, prior to their issue, to the contributions and intelligence of two admirable American journals, the *Philadelphia Photographer* and the *Photographic World*, journals to which the *élite* of the American photographic community contribute.

With the research of investigators and experimentalists in the branches of mathematical, physical, and chemical science, associated with photography, thus recorded; the experiences of practical workers set down; the hints, suggestion, and stimulus of art teachers enforced; the

student's difficulties stated and solved; the social, industrial, and commercial aspects of the art and its works discussed and elucidated; the aim and effort, as well as the achievement in every branch of the art, and its applications chronicled, the elements of advancement must be secured. To effect these things is, in our view, a primary aim of photographic journalism; and to carry out this view we steadily labour. So much of the work is that of others, so little, comparatively, beyond gathering, selecting, garnering, and organizing facilities for obtaining the fullest, the best, the earliest intelligence, is our own, that we can speak without diffidence of the result. And if we had any doubt as to the issue of our effort, the tribunal to which we appeal, the public, for whom we labour, leave us little ground for misgivings. The generous recognition in the constant aid and encouragement, the abounding evidence of approval in the growing extent of our *clientelle*, and the commercial success of our enterprise, give us the highest assurance that our aim is approved, and that it is, at least in some degree, achieved.

For the future, we can simply say that it shall not fall short of the past. The aid which has enabled us hitherto to announce progress, to test its reality and value—at times to be its pioneer, and always its aid and advocate—will not be wanting. Where our own personal effort—in experiment and investigation; examination, proof, and test; suggestion, advice, information, admonition—are available, it shall not be wanting. The duty involved here is our life-work, to which all our energies, experience, culture, capacity have been for many years, and will be, devoted. We believe the work is worthy of the effort, and that it cannot wholly fail; and we accept the spirit of Dryden's line that "They, too, had crowns who but endeavoured well." What has been possible in the past shall still be effected; where new elements of efficiency can be secured, they shall not lack. With cordial thanks to many thousands of valuable adjutors—contributors, correspondents, and readers, we conclude, wishing each a happy and prosperous coming year.

JANUARY, 1872.

THE PAST YEAR.

PHOTOGRAPHY during the past year, as in several preceding years, has not been distinguished by any especially noteworthy discovery or startling novelty. Its progress has, however, been steady and satisfactory. The active brains and lissome fingers which at one time were engaged in searching out its novelties and possibilities have, of late years, been more especially devoted to securing its highest excellence within its known range, and also to extend that range of excellence. Besides this, the extent and multiplicity of the applications of the art have been much increased, and, in some respects, its capabilities have been satisfactorily enlarged.

Whilst no cardinal changes have been made in the general practice of photography during the year, many modifications, materially influencing results, have received attention, and some have been generally adopted. The manufacture or preparation of collodion has not been much modified during the year. The free use of bromides continues with advantage. In some cases there has been a tendency amongst men of experience to abandon the system of maturing collodion by keeping before use, the employment of alkaline salts in the collodion, and its use within a few weeks after iodizing, being adopted; but in the majority of hands the ripening system is found to answer well. The nitrate bath has not been the subject of any proposed modification during the year: its use as nearly neutral as possible, and, in some cases, alkaline, has been found by many photographers to possess advantages, although with a freely bromized collodion the addition of nitric acid is not found to reduce sensitiveness. Developing solutions remain in the position they have occupied for a few years. The use of organic additions is occasionally found valuable where great intensity is required, but for the most part a simple iron solution with acetic acid newly mixed, or nearly so, is found the most valuable developer for ordinary purposes.

Dry collodion processes have not undergone much change. Estimated by results by the majority of experiences of trustworthy authorities, the gum-gallic process of Mr. Gordon appears to be the favourite. Next in order of favour comes the coffee process, or the coffee and gum process of M. de Constant, the rapidity and excellence of which promise great advantages. The collodio-bromide process has undergone considerable modification during the year in the hands of Mr. Carey Lea, and we have seen very fine results obtained by it. The Taupenot, the Fothergill, and several of the old processes continue to be practised with much success, and generally without modifications.

Printing processes, as usual, have been the subject of more experiment, and, in some respects, more improve-

ment. Silver printing has attained such a high pitch of excellence that, except in the matter of permanency, little room has existed for improvement. The question of permanency in relation to silver stands unchanged. In the production of the prints some modifications of importance have been made. The removal of the free nitrate of silver from sensitized albuminized paper is well known to increase the keeping qualities, no discolouration arising for many days; but it has been found that the paper so washed has yielded feeble, flat prints, without vigour or brilliancy. It has been found that fuming the paper so washed just previous to using it for printing, or using fumed papers in the frame, restores all its capacity for yielding vigorous and fine prints, whilst some other advantages are incidentally gained. Collodio-chloride printing is gaining ground, especially in America and on the Continent.

Carbon printing has been the subject of further improvement. Mr. J. R. Johnson has patented some important improvements in the manufacture of carbon tissues or pigmented papers. By the substitution of saponaceous bodies for sugar in the gelatine solution, greater sensitiveness, greater permanency in the sensitized tissue, and some other advantages are gained, whilst by a still further modification of the same principle, printing ink, oil paint, or other fatty pigment may be introduced into the tissue, and eventually pictures in oil colours developed by means of hot water. Some other improvements are included in Mr. Johnson's patent. His improved methods of working have gradually come into practice amongst carbon printers. Methods of permanent printing have not as yet been very generally adopted by portraitists, but signs of a change in this respect are beginning to be manifest, whilst the Autotype Company has found it necessary to enlarge its constitution to meet the necessities of its growing success. Amongst its licensees, Mr. Sarony has been one of the most successful in producing fine work, and the Military Photographic Establishments at Woolwich and Chatham work the process with the most satisfactory results.

Photo-mechanical printing processes have been active. Mr. Woodbury's process has, after all its commercial mishaps, finally attained a position which promises to secure for it the commercial success which the excellence of the results undoubtedly merits. It has also steadily grown in practical value, greater simplicity, certainty, and excellence, following prolonged experience. Mr. Woodbury has also, during the year, worked out some other novelties in connection with the original idea. A method of impressing a water mark design on paper by simply submitting it to pressure in contact with a gelatine relief is very elegant. A method of preparing a copper-plate for ordinary intaglio printing also possesses much promise.

The photo-colographic processes, with that of Herr

Albert at their head, have multiplied during the year. Herr Albert's process has produced exceedingly perfect results, and on the Continent appears to be successful, but has not been introduced commercially into this country. The *heliotype* process of Mr. Ernest Edwards, introduced just twelve months ago, has attained a high degree of success, both as regards the delicacy, vigour, and perfect half-tone in the results, and the apparently unlimited number of impressions which may be obtained from one prepared printing surface. We believe that it has also been commercially successful.

Modes of ameliorating the inherent or accidental crudities of photographic portraiture have been tried. In the United States, printing through a medium, printing from negatives taken on ground glass, printing from two identical negatives superposed one upon the other, and printing from negatives retouched in various ways, have been attempted. In this country the retouching of the negative has been chiefly resorted to, water-colour and lead-pencil being employed for the work, the latter chiefly, and generally most satisfactorily, as more rarely leading to excessive modifications or injury of the likeness. Various modes of securing a tooth for the pencil have been tried, the chief of which have been the rubbing of the bright varnished surface with cuttle-fish powder or powdered resin, or the use of varnishes drying with a matt surface.

The production of enamel or burnt-in photographs has received attention during the year, but has not yet become general. Mr. Henderson has attained very high proficiency by a secret method, the results of which equal anything of the kind hitherto produced. Mr. Solomon has organized a plan of instruction in the two known methods of enamelling.

An important feature of practice has, during the year, been gaining ground; we refer to the use of a preliminary coating of albumen, tunicare, or some similar body as a succedaneum for the uncertain and difficult process of cleaning plates so as to secure chemical cleanliness. The general verdict appears to be favourable to the new method.

The idea of shortening exposures by the supplementary action of diffused light has been revived during the year, and plausible arguments offered in its favour. Experiment, in the hands of M. de Constant and others, has demonstrated that red light gives the best results, and that a real gain is secured by using it as an adjunct to the white light reflected from the object.

Combination-printing, and methods producing combined negatives, have received attention during the year, and the legitimacy of such combination seems to be generally accepted now by the best photographic authorities. A printing-frame patented by Mr. B. J. Edwards has reduced combination-printing to a mechanical certainty, and offers considerable facilities for prosecuting this class of work.

Improvements in backgrounds have received attention during the year, the conical background of Mr. Kurtz and his system of reflectors, and the alcove background and reflecting adjuncts of M. Adam-Salomon, forming most valuable aids to lighting the sitter, and to a satisfactory distribution of light and shade on background of the portrait, and so helping the production of relief and harmonious balance of tones.

The practice of employing photography as a means of identifying prisoners on their second appearance in any prison, which has for some years been voluntarily and successfully adopted by the governors of several gaols, has now been by order adopted as a part of the general prison practice of the country, and a strange rogues' gallery will be collected, which, possibly, may prove useful to some future Lavater in working the facts of physiognomy into a science.

The imperfections of the present standard sizes of plates used in photography was pointed out by Dr. Liesegang, and a new series of sizes proposed combining convenience,

economy, and symmetry. As yet no specific result has followed the suggestion. A new size of portraiture has been proposed and partially adopted in the United States. It is between the usual *cu t* size and that of the cabinet portrait, the print measuring four inches and three-eighths by three inches and a quarter. It has some desirable points, but has not yet been adopted in this country.

The photographic exhibitions of the year have been generally successful. That in Paris was unfortunately brought to a sudden termination by the war; that of the National Association in America was very successful; that in Conduit Street, under the auspices of the Photographic Society, was the best we have seen, having an unusually fine collection of pictures of high artistic merit in every style. Minor exhibitions in the provinces have generally been good.

An important eclipse of the sun, total from various stations in the Mediterranean, was anticipated by men of science as an opportunity of settling various moot points. The photographic observations were successful.

Photographic societies have not declined during the year; in most cases they have preserved the *status quo ante*. The Photographic of London is decidedly reviving, and looks now more promising than it has done for some years. The renewal of the system of holding an annual exhibition may be regarded as having chiefly initiated this improvement.

Photography has played its part in the terrible continental war which has raged for six months between Germany and France, as well as suffered by the war. Besides the use of photography for multiplying maps and similar documents, it has been employed to produce microscopic copies of letters and dispatches, for transmission by carrier pigeon and otherwise, and has been of great service. The suspension of production, in France, of many articles of photographic use, has been a cause of inconvenience and loss to photographers.

REMBRANDT EFFECTS.

MR. KURTZ, in the advance sheet of the *Philadelphia Photographer* with which we have just been favoured, discusses the subject of "Rembrandt effects" in photographic portraiture, the desirableness of the said effects, and the fitness of the name by which they have been distinguished, having been called in question by various writers. Mr. Kurtz, who is, as our readers know, the originator of the style, and one of the most artistic portraitists in the photographic world, ably defends the effects and their nomenclature. The name is not, we think, open to much objection. It is striking enough to attract attention, and is not inappropriate. Rembrandt was a great master of light and shade, delighting in the magic brilliancy obtained by a small proportion of light amid masses of half shadow and deep gloom. In the Rembrandt portraits, flesh and light draperies are kept, as much as possible, in mezzotint, instead of a tint light enough to rob them sometimes of roundness and detail, and render them chalky, a style too common in photography. There is generally a small portion of pure light, which, by its concentration, gives a Rembrandtish characteristic to the picture.

Our chief object, however, in referring to Mr. Kurtz's able defence of these effects, is to quote his reply to the remarks made a short time ago by the "Old Photographer." After protesting against a judgment on the subject being formed upon isolated, and possibly inferior, examples of this style, and pleading the approval of high authorities in evidence that he has not, in carrying it out, "o'erstepped the modesty of nature," Mr. Kurtz quotes the "Old Photographer's" words, that "ordinary faces, lighted in an ordinary manner, will always be ordinary." To this he rejoins, "Very true; I am also of this opinion; but he should, however, have done me the justice to remember that, in that same letter (the one written to the *Berlin Photo-*

graphic Journal), I distinctly stated that it will be an absurdity to light all faces in this way. I believe it is generally known that my sitters are placed upon a movable platform, which allows of being so adjusted that the light on the sitter may be varied at pleasure. In order to further convince your correspondent that I do not light all my subjects in what is called the Rembrandt style (although I was the first to introduce it, which naturally creates an interest in this direction), I will send you a dozen or so of my imperial cards, that you may plainly see the *old style of lighting* (!) is not neglected, and that the pictures which consist chiefly of shadows and half-shadows, and in which the lights are sparingly introduced, are not such absurdities as your 'Old Photographer' makes them out to be."

Referring, further, to the incongruities which unusual lighting is alleged, by the "Old Photographer" and some others, to produce, he adds: "If they think my manner of lighting 'makes the cook suggest the idea of a Lady Macbeth,' I am very much afraid that *their* style of lighting will make the Lady Macbeth suggest the cook."

The truth here, as in many other matters, is found in seeking the *juste milieu*. Mr. Kurtz has introduced a very effective style of portraiture, which, in his own hands, we feel sure will never be misused. He has also suggested to many of his brethren that photography is capable of much more variety of effect than they imagined; and, in trying their new-found power, some of them may possibly, at times, produce curious incongruities. This certainly derogates in no wise from the value of the novelty, which, judiciously used, is effective and pleasing, and affords much scope for the exercise of taste and judgment in portraiture. We shall report on the further examples of Mr. Kurtz's style when we receive them.

BROMIDE IN THE TONING BATH.

A CORRESPONDENT of our excellent contemporary, the *Philadelphia Photographer*, Mr. C. E. Taylor, in the advance sheet with which we are favoured, states that he has found bromide of sodium a valuable agent in the toning bath. His instructions are as follows:—

Neutralize sufficient gold with bicarbonate of soda, for your prints, and when ready to tone, add to the water the prints are immersed in, three or four drops of bromide of sodium. Then add the gold. Tone the prints, leaving them warmer in tone than desired, as they dry up darker. Fix as usual.

I keep the bromide of sodium in solution, about seventy-five grains to the ounce of water. This amount will last three or four months. I have always found this bath to tone readily, and give rich brown or chocolate tones. The more sodium the more red the tone. Use a fresh bath every time. When prints are over-printed, this bath is excellent, as you can add a little more sodium and gold, and the richness will be preserved and the prints toned as light as you want. It gives no harsh contrasts. This bath also gives beautiful tones to porcelain pictures.

This addition to the toning bath is altogether a novelty. The presence of iodine—or, rather, of iodide of silver—is well-known to be inimical to toning operations, the use of an old negative bath from which the iodide has not been thoroughly eliminated often arresting toning operations altogether. The mode in which the bromide acts appears to be as a restrainer, the advantage being, apparently, that being able to add a definite limited proportion to the bath, sufficient restraining action is obtained to secure rich warm tones without arresting altogether, or too seriously retarding, the deposition of gold.

PHOTOGRAPHY AND THE ECLIPSE.

NORWITHSTANDING the unfavourable weather which prevailed at most of the posts of observation, the photographic operations of at least one of the observing parties were completely

successful. Lord Lindsay writes to Mr. Browning at follows:—

"DEAR MR. BROWNING.—We have had very good success. Nine photographs during totality—two of corona, flames, &c., and one having Baily's beads, corona exposures 17.5 sec. and 20 sec.

"Polariscope.—Plano of polarization 23 deg. from Vestes towards the west. No appearance of polarization just before and after.

"Mr. Brown could not find any line in the corona, but a continuous spectrum—no dark or bright lines.

"I had four gentlemen sketching the corona, and one with a position circle and a telescope, measuring the angles of the prominent streamers of the corona. These, compared with naked-eye drawings, tally remarkably well.

"No time for more.—Yours very truly,

(Signed)

"LINDSAY."

Mr. Beasley, who was with the party at Gibraltar, was not able to effect anything, nor have we heard of any photographic results elsewhere.

ENLARGING BY ARTIFICIAL LIGHT.

BY M. HARNECKER, OF WRIEZEN.*

A good stout paper of a rough description, and sized, is in the first place prepared with a facing of gum and sal-ammoniac, made up according to the following formula:—

Best gum-arabic	1 ounce
Sal-ammoniac	1 "
Citrate of soda	1 "
Distilled water	50 ounces

To this mixture is added, drop by drop, as much of a saturated solution of citric acid in distilled water as will impart to the former an acid reaction.

The paper is treated with this solution by floating thereon for a couple of minutes, and may, in this condition, be preserved for any desired period. For sensitizing, the prepared sheet is treated with a silver solution made up of—

Water	100 parts
Nitrate of silver	5 "

to which ten drops of the saturated solution of citric acid are added for every fifty ounces of liquid. The operation of sensitizing requires a period of three minutes, and should be conducted by the light of a small taper; a slight artificial warmth is required to dry the silvered paper.

Before enlarging, the picture should, in the first instance, be sharply focussed, by means of the artificial light, upon a plain sheet of paper, and a small proof obtained, for the purpose of testing the nature of the image. The amount of pose is governed entirely by the quality of the negative, and, according as this is more or less opaque, so the exposure varies from five to fifteen minutes. No evidence of the image is seen before development, the sheet of paper, after exposure, being placed in a mixture of two solutions, to induce its appearance. It is thus compounded:—

No. 1.—Distilled or rain water	...	266 ounces
Acetate of lead	...	3 "
Solution No. 2	...	½-ounce

The whole mixed and filtered.

No. 2.—Alcohol	...	8 ounces
Tannin	...	1 ounce
Gallic acid	...	1 "
Glacial acetic acid	...	½ "

This second mixture, when perfectly dissolved, is filtered, and added to No. 1 in the proportion above specified.

The silvered side of the exposed sheet is placed upon the developing solution, care being taken that no traces of the liquid soil the back of the paper, or that the bare fingers come into contact with it, as stains and spots will inevitably result therefrom.

The operation of development must be carefully watched;

* *Photographische Mittheilungen.*

the image will appear of a clear and delicate nature, and when the necessary amount of vigour has been attained, the process is at once discontinued. The print is withdrawn from the developing bath, and placed forthwith into a vessel of fresh water, the impression being washed with great care, and the water supply renewed from time to time, until all trace of the solution has been removed.

The tone of the picture, in this condition, will be found to be that of a brilliant red; should a more blue or violet tint be desired, the picture may be toned in an old gold bath in which albuminized prints have been manipulated, diluting the bath in the first instance with water to the extent of about one-third its original bulk. The toning-bath must on no account be a strong one, for in this case the delicate whites of the picture are lost—or, at any rate, injured—and the print assumes an unpleasant grey tone.

The apparatus which I employ for enlarging is furnished with the same kind of lighting arrangement as I described, some time since, to the members of the Berlin Society for the Advancement of Photography, excepting that the magnesia cylinders are produced in a somewhat different manner. Carbonate of magnesia and carbonate of lime are taken in equal proportions, and of burnt chalk one eighth part; these are powdered, and moistened with a very little water, and then formed into cylinders, which serve for burning in the ordinary way in the oxy-hydrogen flame.

HOW TO TAKE PICTURES OF THE SUN AND ITS SPOTS AT A VERY LOW COST.

MR. S. R. HATCH sends to the *Photographic Bulletin* the particulars of the very simple method by which the spots of the sun may be photographed.

He says:—"I had an old $\frac{1}{2}$ -size camera-tube, from which I removed the back lens; the front lens was $13\frac{3}{16}$ inches focus. At this point of focus is placed a lens of $\frac{1}{4}$ -inch focus; one quarter of an inch in front of this lens is placed a diaphragm of $\frac{1}{16}$ inch aperture; two inches back of front lens I use another diaphragm of $\frac{3}{8}$ of an inch aperture. The whole is mounted in a tube made of stout brown paper, pasted several thicknesses around a pattern whittled from a stick of wood, making quite a nice tube. This I mounted on a camera-box, the same as any camera-tube. The focus is obtained by the rack on the front tube, and the size of object by moving ground glass. In regulating time of exposure, I use a piece of cardboard, with a slit $\frac{1}{2}$ of an inch, and rubber spring, same as has been published a number of times, a weak developer, and collodion with as much contrast as possible.

"Of course, this instrument is not achromatic, and a picture made at the visual focus will be anything but sharp. Focussing at the yellow ray, just tinged with blue, will make the sharpest picture. A sharp image of the sun, 15 inches across on the ground glass of my camera, can be got; I have not tried to make a negative of that size.

"By putting a piece of white cardboard in place of the ground glass, and looking into an aperture in the top or side of the camera, you can show a very bright and clear image of the sun and its spots."

ON THE VALUE OF UNSERVICEABLE COLLODION.

At a recent meeting of the Photographic Society of Berlin M. Kruger drew attention to the value of unserviceable collodion, and the best means of utilizing it. With some operators, the quantity of this material which accumulates is so small as, perhaps, scarcely to warrant any particular consideration; but in some of the larger firms, in the principal cities of Europe, the amount of waste collodion is, from time to time, very great indeed. Hitherto the only employment made of old collodion has been for plate cleaning, and as a source of burning in the spirit lamp. Irrespective of the

danger of its application in the last-named capacity, from the highly volatile nature of the ether, there are two other very serious drawbacks to its use in that direction, viz., the evaporation of the iodine contained in the collodion, and the tendency of the pyroxiline to stop the action of the wick.

M. Kruger proposes to throw down the pyroxiline in unserviceable collodion by the addition of a large quantity of water, and to use this material again, after thorough washing and careful drying, in the preparation of a further quantity of collodion. The liquid portion, consisting of alcohol, ether, and water, is treated with a large quantity of common salt, and well shaken, an operation which has the effect of separating the mixture into two separate layers, the lower one being a watery solution of salt, and the upper one a compound of ether and alcohol, containing some water in admixture.

These two liquids are separated from each other by means of a separating funnel, or syphon, or other available means, and placed in two vessels, the ether and alcohol being afterwards shaken up with highly burnt potash, to absorb all the water still existing in combination with the spirits. In this way of proceeding the alcohol and ether are extracted in good condition, and the pyroxiline also, so that both these costly ingredients may be used again for the preparation of fresh collodion: the only thing actually lost is the iodizing solution.

In reference to M. Kruger's remarks, M. George observed, Hardwich had given the matter his consideration, and proposed to shake up the collodion with caustic potash, so as to effect the saving of the ether and the alcohol, without, however, paying regard to the gun-cotton. M. Pfeiffer was of opinion that the pyroxiline thus separated would, in all probability, exhibit different qualities from those possessed by it originally, and might not, possibly, be suitable for the preparation of collodion. According to the recent observations of M. Camuzet, pyroxiline, on its solution in alcohol and ether, is separated into three bodies of a different nature, one of them being soluble in water; and if this is really the case, the pyroxiline recovered from old collodion would not contain in its composition the body known to be soluble in water.

M. Kruger, in reply, stated that he could not implicitly rely upon Camuzet's results, and believed it probable that the employment of precipitated pyroxiline from old collodion would be an improvement in the manufacture of a new material; and Dr. Stolze was of opinion that no decision could be arrived at on the subject until actual experiment had been made of the two descriptions of gun-cotton, an investigation which will be undertaken by the experimental committee of the Berlin Society.

ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

NEW YEAR'S GREETINGS—THE WEATHER—PHOTO-MICROSCOPIC DESPATCHES—COPYRIGHT—DEATH'S DOINGS—THE ECLIPSE AND PHOTOGRAPHY.

BEFORE my greetings can reach those to whom they are addressed, the Christmas bells and the new year chimes will alike have ceased to echo, and the new year will be a week old; nevertheless, I avail myself of the opportunity to offer very cordial new year's wishes for success and prosperity to all my readers. The aspect of matters does not, unfortunately, do much to second the cheery character of greetings. The month which is just passed has been, without exception, one of the least favourable, photographically, that I remember during my experience in the art, and it is not now, nor promises to be very speedily, any better. With the thermometer at zero, and thick fog in the atmosphere, the photographer cannot very well be jolly, and I must confess that I derived very little consolation from the remark of a friend in my studio, to the effect that the weather was worse even for trench-work or out-post duty before Paris than for the photographer.

Photography, it seems, continues to play its part in the war. Photo-microscopic copies of communications are now regularly employed by the beleaguered citizens for communication by pigeons and by other means. Let us hope that some of these doves will shortly reach Paris with an olive leaf in place of a war dispatch.

If the question of copyright has not been discussed *usque ad nauseam* in your pages, I should like to say one or two words in rejoinder to Mr. Cunnington, who comments on some of my remarks. He thinks that the discussion has not illustrated the uncertainty and complexity of the copyright laws. He thinks these laws could scarcely be made more simple. This is certainly an odd opinion. The fact that Mr. Cunnington, who writes ably, has taken, and been granted, I scarcely like to say how many columns to elucidate the subject, and that it will probably require nearly as much space to point out many of his manifest errors, I cannot accept as evidence of simplicity in the subject; nor can I, apart from such evidence, believe that a matter which should be as clear as a man's right to the crop he has sown on his own land, which yet requires reference to something like fifteen distinct Acts of Parliament, is as simple as it can and should be. In one sense the matter is simple: if Mr. Graves, or Mr. Brooks, or other art publisher, purchase the right to publish a picture of the producer of that picture, it is very clear to the simplest comprehension that if William Sykes or the Artful Dodger, neither of whom have paid for any right in the matter, make copies and sell them to the detriment of Mr. Graves or Mr. Brooks, they are guilty of dishonesty. It may be that owing to some irregularity, or omission, or other flaw in the title, the legal remedy may not be easily applicable, but the dishonesty is just the same. Than this, I think, nothing could be more simple and clear.

Death has thinned the ranks of photography seriously this year, and has been especially busy with the initial men. Niepce St. Victor was essentially one of this class himself, apart from his connection with Nicéphore Niepce, the first successful photographer. There is no doubt, I think, that Mr. Bingham was the first to use collodion in photography, although he did not invent the collodion process. Now the Rev. J. B. Reade has left us, and to him, I think, there can be no doubt, is due the production of the first developed photograph of which there is any record. The solar microscope image of a flea, which Dr. Diamond can remember seeing on the day of King William the Fourth's death—in June, I think, 1837—was produced by the aid of gallo-nitrate of silver. How great the discovery, how transcendantly important, it is probable he did not estimate; but we know now, and should honour the shrewd and untiring experimentalists to whose labours the existence of the art is due.

It is satisfactory, after the narrow escape which England had of being recreant in the cause of science, and neglecting to take steps for observing the late eclipse, to learn that photography has played so successful a part in obtaining the results of at least one of the parties. In the advices from Catania, where I believe Mr. Brothers was in attendance, no mention is made of the photographic results. In a communication from Oran, I notice that "a photographer, with a camera arranged so as to follow the sun's motion, was ready to obtain views." Photography is of too little importance, apparently, to render it worth while to mention the name of the photographer, although the names of all the other observers of the party are mentioned. However, the elements were unpropitious; a dense bank of clouds obscured the sun during the most important part of its eclipse. A photograph was taken of the earlier stages; but that was all. Professor Janssen, who had escaped from Paris in a balloon in order to be present at the best point of observation, had his labour for nothing. Lord Lindsay and

his party appear to have been the only successful observers, and he, I understand, obtained nine photographs during totality, and these will be of vast importance in aiding to settle the still mooted points as to the nature of the corona.

Every now and then thoughtful photographers appear to devote themselves to considering the possibility of producing photographs in natural colours, and the tendency of thought is undoubtedly opposed to the idea that photographs in natural colours will ever be produced. Mr. Thomas's able communication is very conclusive. And yet I have heard some, in commenting upon the matter, dispose of all objections by the remark, "But the thing has been done; photographs in colours have been produced by Niepce de St. Victor and others;" and your own results, Mr. Editor, have been mentioned as confirming the possibility. I must confess myself one of the sceptics: I do not think that photographs in natural colours will ever be produced, nor do I think that any of the results yet produced afford evidence that they will. I think it was Mr. Swan who first pointed out that all the reproduction of colours as yet effected were simply the result of variation in intensity in the action of light, and where they chanced to repeat a natural colour, it was due to coincidence. Further, it is to be remembered that the colours which have been obtained are a few crude positive colours without gradation or mixture of tints, and that such results are valueless in art.

The South London Photographic Society held its annual dinner the other day at St. James's Hall Restaurant, and spent a pleasant evening, M. Adam Salomon being one of the guests. These occasions are so pleasant that I think it is a pity that they are not the rule with all photographic societies. The annual meeting of the Society was held during the month, and afforded an admirable example of activity. The annual report of the committee, and that of the treasurer, were read; the officers were elected, and various points of a business character attended to; and in addition to this two papers were read, and an interesting discussion on combination printing carried on. At the Parent Society Mr. Pritchard's capital paper on the use of collodio-chloride of silver for reproducing negatives from faded prints was the feature of the evening, the admirable examples exhibited at once carrying conviction. The paper on xylonite, with its new facts about gun-cotton, was very interesting. The provincial societies have also had very interesting meetings.

AMERICAN CORRESPONDENCE.

PRINTING TRANSPARENCIES ON GUM-TANNIN PLATES—
ANOTHER HELP TO RETOUCHING THE NEGATIVE—PERFECT
NEGATIVES WITHOUT RETOUCHING—ON SOME CAUSES OF
FAILURE IN PORCELAIN PRINTING—THE RYE PROCESS
PATENT.

Printing Transparencies on Gum-Tannin Plates.—It would be a great advantage if one could have an easy and simple method of printing transparencies for the lantern that could be taken up at any time and worked without much preparation. Again, it would be very convenient to be able to use such a process in the evening or on dark days; particularly at this season of the year, when those who know the charms and pleasures of a good lantern, and how much it contributes towards relieving the tedium of these long winter evenings, have time to devote to such work, would such a process be found a precious boon. I think I can place such a one in their hands, and if they will try it, I think they will agree with me that it is good.

At the last meeting of the Photographic Society of Philadelphia, and of the Pennsylvania State Photographic Society (Phila.), Mr. Wm. Bell, one of our best photo-

graphers, exhibited in the lantern some admirable transparencies of Western and Yo Semite Valley scenery, which were praised by all the members present for their excellent qualities, and especially for their sharpness and beautiful tone and colour. They were printed in contact with the negatives by means of magnesium light or gumm-tannin dry plates, and as Mr. Bell has kindly favoured me with the details, I append them pretty much in his own words.

Collodion.—Any old and thin collodion will answer.

Silver Bath, forty grains, acidified with nitric acid.

Preservative Solution.

Gum-arabic	20 grains
Rock-candy	5 "
Tannin	10 "
Water	1 ounce

Developer.

Pyrogallie acid	3 grains
Citric acid	1½ "
Water	1 ounce
Gelatin solution	5 drops

Silver and Citric Acid Solution.

Nitrate of silver	10 grains
Citric acid	5 "

Coat an albuminized glass, sensitize, and then put it in a dish of water, film uppermost. Move the dish about until the water flows smoothly over the plate, then take it out and wash it under a stream of water. Now take the washed plate and flow over it the filtered preservative solution. Flow it back and forth well on the plate, drain, flow over it once more the preservative solution, drain, and set it up to dry. Dry spontaneously. Print in a common pressure-frame, the negative and dry plate in contact, by the magnesium light. One inch of single magnesium ribbon is used for each. I also exposed some in diffused light, in my skylight, five seconds, and I think they are equally good.

Now wet and drain the exposed plate, then pour over the plate one ounce of the pyro solution, drain off, and add five to ten drops of the silver and citric acid solution to it. Mix well, flow it over the plate. When developed, fix in hyposulphite of soda, wash well, and dry without heat. When dry, wet the plate with water, and flow over it an acid solution of chloride of gold, one grain to four ounces of water. When toned, dip the plate once more in hypo for a minute, wash well again, dry, and the transparencies are ready for mounting. The gold is not to be neutralized.

Another Help to Retouching the Negative.—As you will notice, continued effort is being made to render the process of retouching the negative easy and popular. I described "Grit Varnish" to you some time ago, and now we have another varnish for rendering a proper surface to work upon to the negative, which was patented in this country December 6th, 1870. I do not suppose it has been patented in England, so I give you the details of its manufacture. The patentee is Mr. J. W. Morgenciu. Two solutions are compounded:—

No. 1.—Absolute alcohol	...	2½ ounces
Picked gum sandarac	...	1½ "
Venetian turpentine	...	1½ drachms
Oil of lavender	...	1 drachm
No. 2.—Absolute alcohol	...	5½ drachms
Sulph. ether conc.	...	1½ "
Gum camphor	...	1½ "
Pure rain water	...	2½ "

Mix the two solutions together by thoroughly shaking them; let the varnish thus made stand a day or two, when it is ready for use, when it may be applied to a contact plate in the same manner as collodion in the ordinary wet process. After the negative is developed, intensified, fixed with cyanide of potassium, washed, and dried, the

plate is coated with the varnish, drained, and set to dry in a cool current of air. When dry it will present a hard, dead, and lustreless surface, resembling ground glass, which can be retouched and worked with great ease and celerity with any grade of pencil from one to five (Faber), or with water colours, or stippling or otherwise.

In varnishing solar negatives, let the plate drain well, and lie, with the varnish side upward, on a perfect level, to avoid streaks. The film on solar negatives does not lengthen the time required for printing.

The photographer should observe the following rules to produce the best results:—

Use no other intensifier than pyrogallie acid, and do not intensify too much, as the negative is intensified to a certain extent by the varnish.

In extremely hot, cold, or damp weather the varnished plate, when dry, may appear spotted; by varnishing it again the spots will disappear.

If necessary to use the plate immediately, allow the varnish to set a few minutes after drawing the plate, and then dry over a moderate heat; but in all cases, the plate must be cool when the varnish is applied.

If the negative has been touched too intensely, the work can be removed without injury to the film by using a soft round camel's-hair brush dipped in water.

This varnish will not crack or peel in the hottest weather, nor will the paper stick to the plate.

Perfect Negatives without Retouching.—As I have said frequently, the retouching mania, so to speak, is liable to work evil, unless care be taken not to use it as a shield for covering careless and imperfect manipulation—i. e., resting upon it, and trusting to it, as the magic power by which all faults arising from haste, laziness, dirty dark room work, &c., may be hidden. I am glad to see, however, that there are some who are endeavouring to make the most perfect negatives in their power without resorting to after-work upon them. Among such is Mr. Chas. Evans, who last evening (Dec. 12) exhibited some unusually fine work from his negatives, which, he rightly claims, are nearly good enough without retouching. I mail you a few of his prints, and you shall be the judge. The following is his method of working:—

Plain collodion	8 ounces
Iodide of ammonium	32 grains
Iodide of sodium	8 "
Bromide of potassium	8 "
Bromide of cadmium	16 "
Bath, neutral	40 " strong.

Developer.

Water	...	64 ounces	} stock solution
Protosulph. iron	...	3 "	
Epsom salts	...	2 "	

Acetic acid about ¼-ounce to 12 ounces of the stock solution. Expose fully and develop slowly.*

The Rye Process of Photolithography.—Mr. Emil Rye has at last secured a patent for his process in this country, and, as his specifications differ considerably from the English specifications already published in the NEWS, I send you a few extracts from the same.

He first describes a peculiar apparatus for drying his "printing plates." It is a rectangular-formed closed vessel on legs, with a post at each corner about a foot in height. Between these four posts canvas is suspended in such a manner that a perfectly inclosed space is formed, which serves as an open or drying space, from which light is partly, and dust entirely, excluded. The lower part of the vessel is filled with water, which is heated by a lamp below, and thus the steam is produced by which the plates in the apartments above are dried. The plate is first albuminized, then "corroded" in a solution of chrome acid, and, while it is still wet, the plate is flowed with a solution consisting of one part of ichthyocollo and

* The examples are very fine.—Ed.

ten parts water, then dried in the vessel described above. After it is dried, it is again made wet with a solution consisting of the following ingredients: water, ichthyocollo, white sugar, chromate of ammonia, albumen, and ox-gall; to this composition add lupulin, myrrh, benzole, and tolu-balsam, dissolved in spirit vini, and further add some drops of a composition consisting of iodide of cadmium, bromide of cadmium, and some more water. The plate is then dried again as before, and after that it is ready to receive the impression from the negative.

The process of transferring to stone or other substance is performed in the usual manner. After the transfer the plate is submerged in water to wash out the salt, and when dry it is ready for printing in a lithographic press in the usual way. I should think it ought to be after such treatment, and I suppose infringers on Mr. Rye's elaborate process will rise up in all directions. The price of ichthyocollo, and tolu-balsam, and lupulin, and spirit vini will also rise—if the others do. Fix it.—Yours truly,

EDWARD L. WILSON.

Philadelphia, December 15th, 1870.

COMBINATION PRINTING FRAME.

BY COL. STUART WORTLEY.

IN an ordinary printing-frame a groove is cut from the top of the wood down to the glass at each of the ends (see A A.) A light frame of thin wood, B B, is then cut and

fitted with two small blocks, either of wood or metal, C C, which work into the grooves A A. This frame is then let down into the printing-frame, and the negative placed in it. The negative is thus prevented moving in any way from side to side, and is further clamped tight by a small screw, E, passing through the side of the frame. D is an

This shows the frame, B B, in the printing frame, and the negative in it. D has then only to be put down on it, and the back springs of the frame closed.

ordinary block for stretching paper on, such as artists use, and on its two ends two small blocks, C2 C2, which are cast from the same model as C C, are fixed, and they also work in the grooves A A. Thus the negative being rigidly held in B B, and the paper stretched on D, the little blocks, C C and C2 C2, working with exactitude into the grooves, A A, cause the same relation between negative and paper to be always borne.

The two frames being fitted exactly alike, the four grooves being all cast from one model, and the eight little

blocks all from one model, the figure negative is placed in one frame, and the background negative in the other, and the two backs, D D, of the two frames being interchangeable, a composition picture can be printed, and the two backs shifted from frame to frame as often as may be liked during the printing, being certain always to return to the same exact position.

An arrangement like this was first made by me to print opal glass pictures some years since, the opal glass being secured by a small catch on to the board; but since, during the past few months, composition printing on paper has attracted so much notice, it may be of use to printers of composition pictures on paper.

I should mention that the ordinary springs of the printing-frame when closed down press the board, D, against the negative in the same way as they would the ordinary back; and when common, and not composition, printing is required, all the apparatus I have described takes out, and the frame is used in its ordinary way.

PHOTOGRAPHY AT CHATHAM.

BY W. DE W. ABNEY, R.F.

PHOTOGRAPHY is, most undoubtedly, double-faced; or, perhaps, to speak more correctly, double-garbed. Her garments are the artistic and scientific. It is the former she chiefly dons in places like the Conduit Street Exhibition, where poetic landscapes and the human face divine are seen as drawn by her pencil. Even there she cannot hide her other dress entirely, but now and then it will peep out unknown. It is of the former dress then that the public knows the most; pure and beautiful, in the productions of a Blanchard or Robinson, or soiled, torn, and almost undistinguishable in the work of the cheap "Photographic Artist." It is on eclipse expeditions, or on such like occasions, that she wears her dress of science outside, and here it is that, if she is not most beautiful, she is most useful. An application of her resources in this aspect I have lately had to make with good success. Some few months ago a Special Committee of Royal Engineers was appointed to take the subject of torpedoes under consideration. To investigate the laws which govern explosions of (Professor Abel's compressed) gun-cotton has been their principal aim. Experiments were instituted by the Committee to practically ascertain these laws, and here photography has stepped in and aided the enquiry. The Royal Engineer Photographic Staff at Chatham were called upon to register the columns of water raised by different charges at different depths of submergence. The following details of experiments may prove interesting:—

Towards the end of September, at about three in the afternoon, was the first experiment. It took place in the Medway, off Chatham. The charge was ignited from, and the photographers on board the torpedo ship *Volta*. The day was bright, and the light highly actinic; using Dallmeyer's rapid rectilinear lens, with No. 2 stop, the picture of the column of water was over-exposed. But still the negative was very fair. The time of exposure was as instantaneous as we could make it. The photographic staff were next called on to photograph the explosion of Whitehead's locomotive torpedo against the hulk, the *Aigle*, at Sheerness. Unfortunately for us, the sea was high, and the officials on board the *Oberon* (the vessel from which the experiment was made) were unacquainted with photographic requirements. The result was, we had seven minutes, after scrambling on board, to get our traps unpacked and a plate sensitized. The sailors had left our tent legs behind! Even under these difficulties we got fair results; if not quite perfect, at all events quite sufficient to register the volume of water thrown up. It must also be borne in mind that the *Oberon* was approaching the hulk some eight or nine knots an hour. As we were placed at her bows, a most decided upheaving was perceptible. The next explosion we registered was in the end of October, and took place

before Mr. Cardwell and H.R.H. the Duke of Cambridge, off Chatham and from the *Volta*. This time we used No. 3 stop with good result, as the day was free from haze, and the light actinic.

The last explosion of which I will give details took place in the snowy weather. We were landed on the banks of Saltpan Reach, off Sheerness, and the charge was fired from the *Volta*, which had been moored there for the experiment. The explosion took place at nine in the morning, before the sun was well up in the heavens. During the exposure it was snowing slightly. We used No. 1 stop with the same lens, and got a good picture. In this last case I had calculated that we should require about twelve times the exposure we had required before. I made it equivalent by using the larger stop, and getting away from the charge double the previous distances. In each case we endeavoured to get the volume of water thrown up at its greatest elevation. This we succeeded in doing in every case, by means of using more than one camera. The exposure given would have fixed a gull on the plate with ease, and these experiments have confirmed me in my previous opinion that Mr. Robinson's gulls were not stuffed. The developer we used is as follows:—

Proto-sulphate iron	60 grains
Glacial acetic acid	10 minims
Water	1 ounce

The nitrate of silver baths were forty grains to the ounce. The collodions used were Thomas's for some plates, and a sample I had specially prepared for the rest. To Q.M. Sgt. Instructor Phillips is due, in a great measure, the success of the records.

Interesting as these pictures are as photographs, they are of more practical value than at first sight appears. Previous to these experiments I had endeavoured to investigate mathematically the explosive effects of gun-cotton fired under water. So little being known of the quantity or quality of the gas generated and heat evolved, it required some practical measure of force to make the formula I had deduced applicable. This measure I got from the photograph of the first explosion, for then, as on each subsequent occasion, a known length placed across the flag, indicating the locality of the centre of the charge, was marked on the ground glass, and thence a scale of feet drawn up for each separate negative.

I am happy to say that every explosion has fixed more certainly the truth of the formula, and I could never have arrived at a practical solution of the problem had I not called in photography to my aid.

I see in Mr. Baden Pritchard's remarks on carbon printing he mentions that the whites of prints are injured by new plates. This I can fully confirm. The enclosed specimen shows the adherent dirt. I have also sent the print in order to point out a remedy for the crapiness that exists frequently in carbon proofs after the second transfer. The print was covered with a network all over the shadows and background (which you see is dark). I soaked the print for two or three minutes in water of 110°. The gelatine swelled, and, after drying it, you see the result obtained. The cracks are filled up, and I doubt much if you could tell that it had previously been faulty. I find that this plan answers well in most cases.

We use the ready sensitized tissue, which we find a great economy in labour.

DEVELOPMENT PRINTING BY ARTIFICIAL LIGHT.

BY W. T. BOVEY.

It was once remarked by an eminent economist, that a man who succeeds in making two blades of corn grow where only one could previously be produced is, to all intents and purposes, a benefactor to his race. By a similar rule, but in a more limited sense, it might be said

of those who have taught photographers the way to turn the dulness of drear winter to profitable account, by substituting artificial for solar light, that they also are benefactors who are deserving of the best thanks of all who profit by the gratuitous instructions they have received. The number of photographic practitioners who avail themselves of the opportunities offered of remunerative employment in the practice of development printing is, doubtless, very limited. This, I believe, is not due to indifference, but to difficulties which make the working of the process a source of uncertainty and loss, rather than one of satisfaction and gain. The causes which lead to failure are, however, within reach, and an examination of those causes at once shows that photographers have only to modify their mode of working to make development printing an operation as easy and certain as the producing of a collodion positive.

Having devoted several evenings, recently, to experiment, and in studying the conditions that lead to success, it has occurred to me that a few remarks, bearing on the subject, from my pen, might render some assistance to those who try, and fail.

Approaching the subject at its beginning, I am compelled to observe that the course usually taken by those who engage in development printing is nothing short of wrong. If, for a moment, they would devote attention to the similarity that exists in the production of a developed image on a collodion plate and one produced by like means on paper, it would directly be observed that the means usually adopted to obtain the latter would, if employed in the former instance, insure nothing but fog and disaster. Instance the silver bath used in development printing, how inordinately large is the amount of acid recommended. Apply such a solution to a collodion plate, and judge the increase of exposure such addition would make imperative. Again, examine the empiricism exposed by some of the salting formulæ. Of what possible use can be an addition of chlorides? Why, none whatever, as artificial light, except an unnecessarily long exposure is given, does not make any impression on chloride of silver. An addition of a chloride can, therefore, effect no good, even though it may not work any positive harm.

The brushing and messing with a sparing quantity of solution I like not: it is an economy that often combines with loss. A very reasonable reply to my objection might be found in the assertion that brushing on the silver solution prevents a large bulk of bath from being contaminated with organic matter. I reply, that an organic tissue that combines chemically with silver should never be employed in connection with printing wrought by developers; for not only does the organic matter render temporarily useless the silver solution, but it also occasions the staining of the paper whilst under development, to a degree that admits of no subsequent remedy. The reason why mention is made of an organic addition in the formulæ for development printing is to provide against the sinking of the image into the body of the paper. The cause of the picture being in, and not on, the surface of the paper is easily shown: the prominent fibre that makes the paper surface absorb but little of the sensitive medium, whilst the pores are filled to saturation; consequently the strength of the image rests where the largest amount of building material is provided; hence the cause of a strong image being seen when the paper is viewed by transmitted light; thus the reason why reflected light exhibits a picture faint and useless. This explanation certainly proves the necessity of filling up the pores of the paper previous to sensitizing. I must, however, for reasons given, question the propriety of employing such materials as gelatine, isinglass, or arrowroot, or, indeed, any substance that combines chemically with silver to the detriment of its working qualities. There are, certainly, papers which need no extra sizing; unfortunately, such papers, on account of their non-absorbent properties, are the least sensitive; the

softer papers are, therefore, the most suitable, and, under proper treatment, are best capable of producing the most satisfactory image. I must not, however, dwell further on this matter, or space will be exhausted ere I enter on details of a practical nature.

Concerning the preparation of paper, for obvious reasons I am compelled to silence. Few prepare it for themselves, and I have a decided aversion to touch on matters of "shop;" I therefore proceed with the working directions I have to offer.

In strength and purity the silver solution should in all respects be similar to one intended for a negative bath; one drop of acetic acid, pure, to five or six ounces of solution is ample. Float the paper not exceeding one minute, if an unsized paper is used, but a paper which has its pores blocked should be floated from four to five minutes. In either case, expose whilst the paper is damp, better wet. And here follow remarks on exposure, to which careful attention is requested, as the quality and colour of a developed print depend more on exposure than on any previous or subsequent operation.

The characteristic of prints as usually produced by development is a granular coarseness and an displeasing colour; these defects arise chiefly from under-exposure. Although a great latitude in exposure is doubtless admissible, yet it should be borne in mind that the right treatment will always give the best results. The range of tints that depends on exposures is from an unpleasant dusky green to absolute red; between these two extremes lie black, purple-black, chestnut-brown, and so on as with the colours produced with a gold toning bath. With such a wide choice before us, it would prove advantageous to the printer if, by way of experiment, he were to modify his exposures, and run the whole scale through; the proper time of exposure to secure the required colour would then be understood. The most satisfactory result is given when the image develops red up to a few points within the finish; the black deposit which follows tones and imparts the requisite depth to the picture at one and the same time.

And now for the developer. Concerning the work of development I repeat. Float. Making the print into a tray may answer in skilled hands, but I am writing for the instruction of those who have no time to master the sleight-of-hand work. The kind of developer used must depend on the paper. A saturated gallic acid solution might in most instances be adopted, and with the generality of prepared papers its use is unquestionably the safest. In my own experiments I have employed pyrogallic acid in these proportions—

Pyro	2 grains
Citric acid	3 "
Water	3 ounces

I have not, as yet, completed my experiments with iron, but hope soon to do so, and to report thereon.

It is at all times best to stop the development of a well-exposed picture a shade or two within the depth the finished image is required, and the washing previous to fixing should be very brief, as development continues even when the paper is immersed in plain water. A little common salt added to the water acts as a break, but I prefer washing briefly, and immersing the print at once into a fixing bath composed of hypo, five or six ounces to one pint of water.

Concerning time of fixing, no time need be stated; the print must be thoroughly divested of unreduced iodide of silver. On many occasions I have received examples of under-fixed prints with a request for information concerning the cause of the yellowness. It must be taken as a rule that as long as the primrose tint is visible, when the paper is viewed by transmitted light, so long does the print remain unfixed. If, when dried, the print shows up yellow, plunge it again into the hypo, and when the print is fixed, if a pleasing finish is desired, a coating of

albumen or encaustic paste improves the picture wonderfully.

I enclose for the Editor's inspection a small print, from a very indifferent negative, which was produced by development. No gold toning nor touching was resorted to. The result differs but little, if anything, from one produced by direct printing. Gaslight was used in its production.

A word in conclusion concerning cleanliness. Success only waits on clean solutions and clean handling. Filter the solutions, wash well the dishes, conduct the operations of sensitizing and developing in a chemically dark place. Observe these precautions, and there remains no reason why success should lie beyond the ability of anyone who may desire to try his hand at printing by artificial light by a process of development.

HOW TO FLAT A BACKGROUND IN OIL.

BY A. L. HENDERSON.

A FEW lines on the above subject may not be uninteresting to many of your readers, for I have failed to obtain satisfaction in that line by the services of professional painters.

In the first place, after having obtained the frame of the desired size, stretch a piece of canvas or calico over the frame, about an inch larger than the outside, and, after tacking it loosely round the margin, size over the canvas with equal parts of size and water. After the calico is dried, paint the surface with—

White lead	1 lb.
Driers	2 ounces
Black paint,	<i>quant. suff.</i> to give the tint required			
Turpentine	$\frac{1}{2}$ -pint

After thoroughly mixing, allow this to stand a few hours until the lead has settled down. The turpentine must then be carefully poured off, which will get rid of nearly all the oil that the lead and driers contained. If much oil is left, it will seriously interfere with the ultimate success of the flattening. Add fresh turpentine to bring the paint to a proper consistency; then add of scraped brown soap two ounces; strain through calico or a sieve, and the paint is ready for use.

A large brush is best, and the quicker the surface of the canvas is painted over the better. In all probability, it will be found that the canvas or calico will have stretched considerably. It must now be tightened, and the tacks may then be permanently driven home. This completes the operation.

Should the ground, after being dried, be found to require another coat, the operation of painting must be repeated.

Correspondence.

NATURAL COLOUR IN PHOTOGRAPHY.

MY DEAR SIR,—I think Mr. R. W. Thomas, in his excellent article in the NEWS, has shown conclusively the impossibility of obtaining photographs in natural colours, and that those photographs which partake of the *apparent* natural colours are only modifications of one colour. Even if the primitive colours could be produced and fixed, *that* would not be sufficient; we could not get the endless varieties of each colour, as seen in nature. Your correspondent, who mentions the "Rosella Parrot," is no doubt right when he speaks of there being some peculiar property in the white feathers, capable, when exposed to light, of absorbing or reflecting certain colours; and it is just this property which is required to produce a photograph in natural colours. If it were possible to discover what that property was, and then to combine every agent on one surface, and also to discover how to develop each delicate variety of colour in its proper place, as in the natural object, then we might succeed; but, as Mr. Thomas remarks, this would be an absolute impossibility.

I noticed amongst my tulips this year a curious instance of *real*

ature-painting in colours. Two tulips, of different colours and markings, had the last leaf on the stem next the flowers with a perfect reproduction, on a green ground, of the colours and markings of the petal to which the leaf had been attached; this leaf, unlike the others, though the same in shape, must have gained the property of reflecting other colours besides green from contact with the petal.

From the description of the prints from Robertson's negatives of "Scenes in the Crimea," I should imagine they must have lost much of their detail, and that, therefore, the reproduction would hardly be perfect. I have several of the original prints, which are perfect still as regards detail, though two or three are yellow-brown. I have the three prints of "Sebastopol from the Malakhoff," forming the panorama; two of the "Redan;" and one of the "Barrack Battery." They are quite as Mr. Pritchard's service, for comparison with his reproductions.—Believe me yours very truly,

THOMAS BARRETT.

Mead Vale, Red Hill, December 27th, 1870.

COPYRIGHT AND PIRACY.

SIR,—Mr. Cunningham is fond of law, and objects to moralizing, but not, I trust, to morality. I know nothing of the law of copyright beyond what I have learnt from this correspondence, so, for argument's sake, I conceded to him every legal point he has claimed; but, in common with your esteemed correspondent, "An Old Photographer," and, I believe, with almost every body else, I came to the conclusion that the law of copyright was miserably uncertain and perplexing, and that, in consequence, the "alleged copyright" of certain publishers had been infringed by some people whom Mr. Cunningham defends. As it was never denied that these copyrights had been dearly bought and honestly paid for, and that therefore they ought to be inaccessible, I did express a pretty strong opinion against the moral, not the legal, right of those who take advantage of an imperfectly drawn statute, to defeat its object and commit a gross injustice at the same time. Of course, while a law is a law it must be respected, however bad it may be. It would be in the highest degree wrong to punish with fine and imprisonment any one who takes advantage of its imperfections. At the same time, we may all hope to see such an imperfect Act improved, and, in the meantime, may look with little favour upon those who commit an assault upon justice with drawn sword. Mr. Cunningham will allow that law is the means, and justice the end, of jurisprudence. If the means defeat the end, so much the worse for us all.

But, alas, sir! I find this argument of mine is all thrown away. I am beating the air, and Mr. Cunningham has cleverly outflanked me. The law of copyright is not perplexing; it is "simple, plain, and explicit." The only reason that a *bona fide* copyright can be impeached is because the publishers and their legal advisers do not know their business. They have no interest in failing to comply with these "simple and plain" formalities. But, miserable men! through laches and sheer stupidity, they fail to do so, and thus throw away thousands of pounds for want of common business capacity. Then, again, the judge and magistrates; they have almost invariably decided in favour of the publishers; or, as in the case of "My First Sermon," quoted by Mr. Cunningham, they "doubt." But the convictions are all bad, and the doubt perfectly uncalled for, the matter is so simple and plain. Mr. Cunningham constitutes himself into a final court of appeal, in which he is at once appellant, advocate, and judge, and decides the case entirely in his own favour. Judges, magistrates, lawyers, your other correspondents, my humble self—I might say the world generally—are egregiously mistaken, and that about a matter "plain, simple, and explicit." *Cunnington locubus est*. Or is it just possible that, after all, Mr. Cunningham's wishes are fathers to his thoughts; that there are some technical difficulties and dubious points of which he, for himself or his clients, is seeking to take advantage? Let your readers judge if there be not at least a doubt about that.

If, sir, you can find space for another word, will you allow me to add that I have acquired considerable respect for Mr. Cunningham's talents as an advocate. His advice to you respecting Mr. Knight's shop is clever and judicious. If I were he, I should certainly say "don't" visit it. He speaks of having seen in it a portrait of Mabel Gray. May I ask if it was one of the charming copyright photographs of Messrs. Elliot and Fry, or Hills and Saunders, or a bad copy of one of their pictures, ticketed threepence?—I am, sir, your obedient servant,

JUSTITIA.

APPLYING PRELIMINARY COATINGS TO PLATES.

DEAR SIR,—I think, after a great deal of thought and experiment, I have discovered a method of applying albumen to plates, by which means you can ensure bright and clear plates, no matter what number you may prepare. When the plates have been cleared of the old films, wash them well, then stand them up to drain and dry; when dry, take a clean cloth and wipe away the dirt which the water leaves on them. Now, presuming the albumen solution to be ready, pour it into a clean basin, or anything you think fit, so you can dip a three-inch camel-hair brush into it; take the plate by the two end corners with the finger and thumb, or, if it be too large, take it by one of the corners, and rest the centre on the neck of a bottle, the bottle standing upright; incline the plate a little, take the brush full, lay it on the plate near the top edge, and draw it gently down the plate lengthwise, not quite to the side edge; fill the brush again, and repeat the same operation again, but be sure to let the brush touch the albumen where you left off; repeat the operation till the plate is covered. Do not hurry, or you will fail to do it properly, for the air-bubbles which stick to the brush will leave it and stick to the plate. If such a thing should occur, go over it again, and that will put all right; but with care and patience, by drawing the brush very slowly down the plate, the air-bubbles will cling to the edge of the brush, and you will have a clear and bright plate.

If anyone else should claim the prior knowledge or use of this method, it matters but little to me, as I shall have the satisfaction and credit of being the first to make it public for the benefit of others. This should be, in my estimation, the maxim of all photographers; and by carrying it out they would be the gainers in the end. If you think this worthy of a place in the PHOTOGRAPHIC NEWS, I shall be glad.

The brush is flat, the hair in tin with a wooden handle; cut the long handle off if you like.—Having the honour to be your humble servant,

E. MARSHAM.

Thetford, Norfolk.

DISSOLVING VIEWS LANTERN.

SIR,—In answer to a letter signed "J. Powell," in a recent impression, on dissolving views (?) with one lantern, I beg to inform that gentleman that his plan is an old one, and is, at the same time, by no means satisfactory. The principle is simply placing another slide in the holder before the first one (which is being exhibited) is withdrawn out of the lantern. Let anyone who has a lantern try the effect, and the result will be anything but gratifying, or even approaching to dissolving. When pushing in or out the slide which is done with, the effect is disagreeable, especially as the edge or frame of the transparency passes over the picture which is being exhibited from one side of the screen to the other. There are various better plans in the "market" for producing dissolving views with a single lantern, or, to speak more correctly, for the purpose of never letting the screen appear a dazzling white blank: to dissolve effectually one picture into another, or to show "effects," cannot be obtained without two lanterns or lenses.

A few months ago, another party, in a very popular mechanical magazine, stated that he had discovered a plan for dissolving, using two lenses, but only one source of light. The principle of that clever savant was to raise and lower the lamp, by means of rack-work, from one lens to the other. "The effects," says he, "are beautiful. I place in the bottom lantern a slide—a rustic picture of morning; the sun is shining, and all nature seems glorious; in the top lantern I place another slide of the same scene, but by moonlight. Now, by the rack-work, I move the lamp (which is oxy-hydrogen) from the bottom lantern to the top one, slowly, however; the sunny picture dies away, and the moonlight one as gradually appears, with all the beauty of a complete dissolving view apparatus."

I offer no remarks upon this, only that it is a shame that men so unblushingly untruthful should rush into print, thereby deluding some whose knowledge of optics and illumination are so meagre that the deception and the falsehood are never found out until after personal experience, dearly bought.—Yours, &c.,

December 26th, 1870.

SILVESTER.

Proceedings of Societies.

GERMAN PHOTOGRAPHIC SOCIETY, N. Y.

GENERAL monthly meeting, November 3rd, 1870; Vice-President OTTO LEWIN in the chair.

After reading and approving the minutes of the last meeting, Mr. SCHÖNE called the attention of the members to the assertion of M. De Constant (*Photographique Archiv*, July, 1870), that, by covering the inside of the camera-box with white card-board, he shortened the exposure and softened the shadows in the negative. Mr. Schöne thought that, in theory, it was highly improbable. He made some experiments on this plan, and found not the slightest difference either way. This settles, at the same time, the old notion, that the camera must be black inside. In experimenting, Mr. Schöne attained the same results M. De Constant claims to have got; in a different way, however—by covering the floor between the camera and the sitor with white card-board. This new style of reflecting had such a decided effect, that Mr. Kurtz ordered at once a white linen cover for his floor, and is using it now with great success where short exposure is wanted.

Several gentlemen said they had been greatly troubled through the summer with irregular transparent lines in the negatives, not unlike a combination of lightning forks. They appeared with all kinds of collodion, old or new silver bath, strong or weak developer; in short, they were perfectly unaccountable.

The debate on this subject elicited the facts, that those lines always appear in the thinnest part of the collodion, no matter which way the plate was immersed, and that they very rarely are seen in a thick collodion. The apparent conclusion drawn therefrom by some gentlemen was, that the cause of it had to be sought in an uneven, too quick drying of the film. Others contended that the collodion was over-iodized in proportion to the strength of the bath. The whole subject was finally laid over for future observations and reports.

Mr. LÖHR exhibited one of his new "Success Camera Boxes" for examination. After a thorough and close inspection it was pronounced, by the unanimous opinion of the meeting, to be the very best camera box in the market. The model meets every requirement wanted, the material is of the very best mahogany, and the workmanship excellent. Every photographer will find these boxes a success indeed. A full description of them will follow soon.—*Bulletin*.

Talk in the Studio.

ROYAL POLYTECHNIC INSTITUTION.—The Christmas entertainment provided at this popular establishment is, as usual, an interesting and amusing one, the several hours of entertainment being fully occupied by the lectures and exhibitions which follow each other in quick succession. Professor Pepper has chosen the Franco-Prussian War as the subject for a seasonable lecture, in which the different arms used by the contending armies are shown and described; some capital photographs thrown upon the large screen help also to illustrate the subject, which is treated by Mr. Pepper in his usual clear and able manner. Tyrolean minstrelsy, by the clever Praeger family, is also an important and very agreeable feature of the Polytechnic programme just now, and there are, besides, conjuring and ventriloquian entertainments to please the more juvenile portion of the audience. But the most pleasing part of all is, perhaps, the *finale*, when Mr. George Grossmith, Junior, recites an entirely new version of "The Yellow Dwarf." The story is quaintly written, and told with much dry humour, being, moreover, interspersed with some capital songs, which keep the audience pleasantly amused throughout. An allusion to chemical science, in which Mr. Grossmith, among other things, describes the double distilled sub-chloride of tin-foil as a monkey-coloured substance, seemed to tickle his hearers exceedingly; the legend forms, indeed, a good finish to the entertainment, and sends the audience home in great good humour.

CLEAN HANDS.—Mr. Anderson, in our Philadelphia contemporary, instructs his pupil how to have clean hands. His pupil exclaims, "How you manage to keep your hands so clean,

is a pez beyond me. I noticed your hands last evening particularly; they were as black as if you had a pair of black kid gloves on, and now they are as clean as a whistle. What do you use? I try to clean mine by first rubbing them with a rag dipped in a solution of iodine, and next rub them over with a piece of cyanide, and here's the result: they look as black as soot." Mr. Anderson replies: "Reverse the operation, and you will have no difficulty whatever. Rub the stains over with a piece of cyanide of potassium under the tap; then rub the cyanide over the whole hands; next pour in the hands half an ounce of a strong solution of iodine in alcohol; rub the hands well together, when you will perceive a slight lather; plunge them under the tap, and wash until all 'greasy feel' has vanished; finally, with soap and water, and here's the result. The silver stains are removed with ease, but with pyro it is a very difficult matter. Use one of those suction-holders for developing. Pyro can be removed by rubbing the stain first with a solution composed of one ounce bichromate potash, dissolved in muriatic acid, diluted with eight parts of water. When the pyro stains are gone, the bichromate leaves a yellow stain, which must be immediately removed by washing with strong ammonia. But all this is very disagreeable and troublesome. Better than all these, don't strengthen at all; redevelop with iron."

THE MODERN PHOTOGRAPHER'S CREED.—The *Period* gives the following as the creed of the photographer:—

I do believe the Castle of Fame
The period has erected,
To be a house of cards, as lame
As ever was dissected;
And that it is a first-rate plan,
When thoughts of fame the phiz heat,
To build your portion while you can
With loads of *cartes de visite*.
I do believe that crime and sin
Are more than bread and cheese to me;
That forgeries increase my tin,
That murders must bring ease to me;
And that this world of rights and wrongs
Those parties best to court rates,
Who can collect the thickest throngs
To gaze upon their portraits.
I do believe myself to be
Superior to the Muses,
Because the popularity
I give, that each refuses;
That fifty volumes worthless are,
Beside a pretty dimple;
That handsome legs pay better far
Than genius pure and simple.
I do believe a fine *cocotte*
Is worth her weight in gold to me;
That modest beauty's simply rot,
Providing it's not sold to me;
That, when burlesque is past and gone,
The Drama will have perished;
Which Impudence and I alone,
In its decline, have cherished.
I do believe that any sale
Of pirated sun pictures
Upon the vendor should entail
The heaviest fines and strictures;
That, since the public is an ass
Remarkable for puerience,
I were his like, did I not mass
Meet food for such esurience.
In short, I do believe the ago
To be that of Photography,
Which preys on anything the rage,
From genius to geography.
Is there an infamy about?
I think my terms will suit him;
And if I catch a pirate out,
Oh, won't I prosecute him!

CLEANING GLASS.—A correspondent of the *Philadelphia Photographer* says:—"I adopt the most simple method, which is generally the best. I adhere to the rotten-stone, alcohol, and water, but the buff leather I have given up. I found old rags to suit much better, and they can be washed more easily when

dirty. I found nothing equal to an old cotton stocking-leg; the twill gives it what artists call a "tooth," a good quality for cleaning glass, and it possesses another peculiarity, which is. I think, of considerable value; it leaves no lint on the glass to be brushed off when you are in a hurry, as most other cotton goods will do. I take my glass after it has been washed, fix it in the vice, and throw on a few drops of a mixture of rottenstone, alcohol, and water; this I rub over the glass with an old stocking, which, if kept otherwise clean, will answer a long time without washing. I then finish with a clean piece kept for the purpose. I feel confident that whoever tries the old stocking will be pleased."

MERCURY FOR INTENSIFYING.—A correspondent in the same journal says:—"I have found nothing in ten years' practice of photography for intensifying as nice and uniform as a little bichloride of mercury, weak solution wash, then apply a weak solution of chloride of gold. The operation can be repeated, alternating between the gold and bichloride, till almost any degree of intensity can be obtained, if you have any detail at all. Wash well between each operation, beginning with the mercury."

To Correspondents.

*** **THE TITLE-PAGE AND PREFACE** to the last volume of the **PHOTOGRAPHIC NEWS**, consisting of four pages extra, are given with the present number.

THE YEAR-BOOK OF PHOTOGRAPHY FOR 1871 is now ready. It contains a larger amount of matter, and a greater number of original contributions, than any hitherto issued.

OUR NEW VOLUME.—The present number of the **PHOTOGRAPHIC NEWS** commences a new volume, in which we hope, not merely to maintain the features which have hitherto secured for it so much prestige and favour, but to add all available means of increased interest and efficiency. Special arrangements for various series of articles of interest are made, and examples of new processes are in preparation. Besides the articles of the regular staff, communications from the able pens of the following distinguished photographers may be expected:—Mons. Adam-Salomon, Mr. Bedford, Mr. H. P. Robierson, Mr. Mudd, Mr. Hughes, Mr. Blanchard, Mr. England, Col. Stuart Wortley, Mr. R. Manners Gordon, Dr. Anthony, Dr. Vogel, Dr. Monckhoven, Dr. Liesegang, Mr. E. L. Wilson, Mr. Cherrill, Mr. Earl, Mr. Rejlander, Mr. Piercy, Dr. Phipsoa, Mr. Spiller, Mr. Baden Pritchard, Lieut. Abney, Lieut. Noverre, Dr. Diamond, Mr. S. Fry, Mr. Bovey, Mr. Dallmeyer, Mr. Tunny, Mr. J. R. Johnson, Herr Grune, Mr. B. J. Edwards, Mr. Ernest Edwards, Mr. Woodbury, Mr. Henderson, M. de Constant, Professor Morton, Mr. Arthur Taylor, Mr. Butter, Mr. Window, Mr. Burgess, Mr. Slingsby, Mr. R. H. Preston, Mr. J. Martin, Mr. Swan, Mr. A. Hughes, Mr. Gulliver, Mr. G. Croughton, Mr. Wyles, Mr. Gillo, Mr. W. H. Davies, Mr. Beattie, Mr. Cocking, Mr. Crookes, "Respice Finem," "The Old Photographer," Mr. Blair, Mr. Notman, Mr. Carbutt, and other contributors.

R. MORTON DAY.—There is no work in English on photo-enamelling, nor, so far as we know, any especially devoted to the subject of enamel painting. The **YEAR-BOOK** is now ready.

R. A.—For the registration of a design, the office for which is quite distinct from the Copyright Registration Office, you must apply to a patent agent. Our publisher has no connection with such duties. You will find the name of a patent agent in the present number.

A SUBSCRIBER FROM THE FIRST.—You will obtain chrome alum from any photographic chemist in London. It is doubtful whether you will obtain it of a local chemist.

PHOTO.—Such a studio as you describe will answer well for general work, but will be rather short for full-length card pictures. You will have to use a lens of shorter focus than is desirable. Two or three feet longer would have answered well.

GLASSHOUSE C. B.—We cannot remember the details of a query made to us some time ago. When a question is answered we preserve no record of it. You must again describe special necessity you wish to meet, and we can then give you a detailed answer. We do not now remember for what especial purpose the lens was wanted.

TYRO.—We are not familiar with the lens in question, but believe it to be intended as a quick-acting card lens.

FOGEX.—All neutral aqueous solutions of chloride of gold are apt to become decomposed and the gold precipitated if they stand in the light; but if protected from the action of light and from contact with foreign matter they should not precipitate unless they have been made alkaline. 2. The chloride of lime bath keeps best. There is no reason to suppose your gold faulty. You may make any toning bath keep by the addition of a trace of hydrochloric acid; this must be neutralized with chalk a few hours before use. 3. M. Adam-Salomon's system of lighting may easily be adapted to open-air use with great advantage. 4. We are not well assured that sulphate of copper has any specific action in development; but being chemically neutral in the matter, it may retard by mechanically hindering the activity of the developing agent proper. 5. You must have erred in some particular, as we have had other reports of their efficiency. The pipe you mention probably would answer, but it is a matter to be determined by trial.

O. S.—It is quite impossible to say which is the best tent. There are several excellent tents in commerce, but much depends on the special want of the photographer as to which is best. Mr. Thomas's tent is most excellent for large work, and is arranged with a distinct recognition of the fact that it will require two persons to carry it. Rouch's tent is also capital for smaller work, and may be carried by one person. And so with various other tents; each has some good point which may suit special necessities. 2. We recently answered a correspondent that enamels might be burnt in a gas stove, but the expense was heavy of such burning. One of Griffin's gas stoves will answer the purpose.

A. Z.—Carbolic acid is most commonly known as carbolic acid. It may be obtained of most dispensing chemists either in crystals or solution. "Tar's glycer-carbol" is sold in shilling bottles by most chemists. It is a solution of carbolic acid in glycerine, and is very handy for use. A few drops will suffice for preserving albumen and similar solutions. The smell is like that of creosote, which may be sometimes used as a substitute. 2. A gramme is equivalent to about 15½ grains. You will find a table in our **YEAR-BOOKS** for some years past to turn grammes into grains. 3. From half a drachm to a drachm sugar to each ounce. It, to some extent, acts as a restrainer, and makes the solution flow evenly.

EX-OPERATOR.—We cannot at this moment refer to instructions for the preparation of lithographic transfer paper and lithographic ink. We believe that the former is made by coating paper with a layer of starch, which leaves the paper on being damped; and the latter is analogous to ordinary printing ink, but diluted with boiled oil. Perhaps some correspondent can give more precise information.

TEMPUS FUGIT.—You will find brief accounts of the origin and history of photography prefixed to several books of photographic instruction. One of the most copious accounts for your purpose is an article in the *British Quarterly Review* for October 1866.

J. MARTIN.—We will write in a day or two.

W. R. P.—You will find allusions to the subject scattered through various articles in the volumes you have got, and you will find articles on p. 529 of Volume IX., and on p. 125 of Volume XI.

M. F. L.—The dirty yellow stains are the result of imperfect fixation. Use your hypo solution fresh, one ounce of the hypo in five ounces of water; and make it with warm water, so that you may use it at a temperature not under 60° Fah. During extremely cold weather the solvent or fixing power of the hypo solution is much diminished.

L. D.—We shall publish full details of the coffee process shortly. It is as simple as the Fothergill process.

G. T.—The negative from which the print you enclose was taken is over-worked upon evidently. It is not badly done, but far too much is done. All texture of flesh is gone, and the texture of wax-work or marble—for these would produce somewhat similar effects in photography—is obtained. The lines under the eyes and down the cheeks are smoothed away, and give a doll-like effect to the face. When retouching not only removes character, but takes away the effect of life, it is a great evil. Judicious retouching is legitimate; but excessive retouching is worse than the crudest untouched photography.

F. M. R.—You will find an article on the subject in our **YEAR-BOOK** just issued.

C.—Snow scenes are very effective in the stereoscope, where the texture of snow and ice are very effective; but except the general characteristics of the landscape are suitable, and aid effects of light and shade, winter scenes covered with snow are rarely pleasing. 2. You may use a 50-grain solution for the winter portraiture, and about twenty minims of acetic acid will be sufficient.

R. SYMONS.—Thanks for your interesting photograph of the eclipse.

TO SEVERAL CORRESPONDENTS.—We offer reciprocations and thanks to many correspondents who have sent kindly reasonable greetings.

Several Correspondents in our next.

THE FIRST ANNUAL INTERNATIONAL EXHIBITION.

SOME uncertainty has prevailed as to the time for making applications for space at the forthcoming International Exhibition, no authoritative statement of the time having ever reached our hands, or been published in our pages. We recently wrote to Col. Scott, the Secretary, for information on this and some other points connected with the Exhibition. In the reply received it is stated that the thirty-first of December last was the limit of the time appointed for receiving applications; but that "any further intending applicants should apply at once."

From this we glean that application made promptly will still receive attention; and those of our readers who are desirous of exhibiting should make application without delay. The time appointed for receiving the objects amongst which photographs are classified is the twenty-first of February next. The committee of selection for photographs has not yet been made public, although the appointment was made some months ago. Photographers may accept our assurance, however, that the three gentlemen constituting the committee are admirably fitted, by long association with photography and distinguished attainments in connection therewith, for performing the responsible functions of their office satisfactorily. We shall publish some further details of interest to photographers in our next.

PHOTOGRAPHY AS A BUSINESS.

PHOTOGRAPHY as science and photography as art are themes familiar to photographic societies and to photographic literature: photography as a business is, as a rule, tabooed from discussion in societies, and is rarely touched upon in journals. And yet it is quite certain that the closest connection, the completest inter-dependence, exists between the different phases of the art; and its satisfactory progress in any of them depends upon its progress in all. In its origin, photography was equally affiliated to science and art. Of the earliest experimentalists, Sir Humphrey Davy was a man of science; Wedgwood had proclivities towards art. In the next more successful essays, Talbot and Reade were men of science; Daguerre was an artist. The legitimate offspring of this auspicious parentage owes its growth, strength, rapid development, and wide-spread application to its foster parent—commercial enterprise. If it had not proved remunerative as a business it could never have assumed its present proportions. If science and art had not watched over it during its development and application, and taken part in its education, it could never have become so successful as an industry.

It is interesting to note the different spirit in which the

business aspects of photography are regarded in two countries. We in England are in the habit of regarding ourselves as a practical people, but no word of the business interests of photography is ever breathed at our photographic societies. At one time a professional photographer was considered ineligible for a seat at the council table of the Parent Society; and it was only the fact that such an arrangement deprived the Society of the active aid of so many of its ablest exponents which put an end to its operation. Professional photographers now join that august conclave, but they leave the business, and all considerations affecting it, at home; and neither in council nor in the general meeting is the subject ever referred to. In America the national association of photographers deals with the interests of photography all round as science, art, and business. To protect the pecuniary interests of the portraitist and improve his status forms as important a part of the functions of the Association as the discussion of processes or the consideration of the modes of securing the best pictures. We have been further struck with an illustration of this practical mode of dealing with matters by the report just issued by the Ferrotypers' Association of Philadelphia. We have before stated that the practice of producing collodion positives chiefly on the enamelled iron or ferrotype plates is still so universal in America that the portraitists devoted to that branch are sufficiently numerous and important to form a society in themselves. The report of a committee of this Association, appointed to consider the best modes of securing success in business, has just been issued. It will be seen, from the portion we reproduce, that the idea is entertained by the committee that the judicious introduction of novelties is the best stimulus to portraiture as a business, and that the cultivation of reticence, secrecy, and isolation of interests is the surest means of securing failure. The report proceeds as follows:—

REPORT OF THE COMMITTEE ON THE BEST MANNER OF CONDUCTING BUSINESS.

It has been customary, in times past, with photographers and ferrotypers, to stay at home professionally, and to keep everything a profound secret with reference to their manner of working; and they would feel highly insulted if their neighbour had courage to ask them for any of their formulæ. Such a principle is very injurious to our business, and ought to be condemned by all who take an interest in the advancement of our art, and the prosperity and encouragement of our best artists. No advancement can be made if every man keeps every new discovery to himself, for when he dies his new discoveries die with him, and we, as artists, receive no benefit from them. Hence our art will actually degenerate.

The true principle for mutual advancement is to organize societies where we can have discussion on all important matters connected with our business, and exhibit our work; and for every artist to do all he can to educate himself and his co-workers. This principle should receive encouragement from all who take an interest in the prosperity of our art and the development of photography.

The real cause of dull times and of the difficulty in keeping up

demand for our work is found in isolation and conservatism. For example: For many years past we have made small vignettes, standing figures with scenery backgrounds, and by fences and posing chairs, and pedestals with curtains, and parlour scenes, &c., with all the accessories that could be thought of. Such pictures have had a great run, and we all did well with them; but gradually our business grew less, and we resorted to every means in our power to increase it. Some lowered prices, thinking it would increase trade, but to no purpose.

Now the real cause of the dullness is this: Everybody has a supply of the above-named styles of pictures, and it is very plain that you want but one picture of your friend of the same style; and when you have supplied all your friends with your picture of those styles, you will have less taken, as you have only new friends to give them to. Consequently, our orders will be smaller and farther between, and our business grows gradually less every year. Now "what must be done?" Some say, "We have too many engaged in the business." That is not the cause. We only want something new. The demand is for something new; and all our best customers ask if we haven't something new. They say, "We have had so many pictures taken this old way; we are tired of them. Give me anything, so it's new."

You all know that has been the cry for at least two years past, and we have only been able to furnish them with what is best known as the large heads, or imitation of the Berlin cards. A few made them at first, and now they are the only style of ferrotype called for in some of the galleries. They are called at different galleries by different names. Some call them "German Head Ferrotypes," others the "Bon Ton," and some the "Large Heads;" but they were christened by the one that first made them the "Chromo-Ferrotype." His reasons for giving them this name was the fine, soft tone when made on the chocolate-tinted plate. Whether this is the best name or not, we feel that it should be named, and that all should call it by the same name. To make a new picture popular and widely known, every artist should call it by the same name.

The way to keep up a demand for our work is to issue new styles of pictures, the same as milliners, and hatters, and dressmakers, and tailors issue their new styles.

After a few further remarks inviting co-operation in securing the ends in view—the contribution of specimens of details of formulæ and practice to the journals—the report concludes by a distinct statement of the business aims of the Association:—

"The object of this Association is to unite all engaged in and associated with our business; to devise means for the advancement of our art; to encourage a better class of work, which will inevitably lead to better prices. And may we see them promoted."

The desire to maintain the status of the art and the artists, and promote the commercial interests of both, is one in which all photographers must join; and the question will probably occur to many whether that might not be better secured by the occasional consideration and discussion of the business interests associated with the practice of the art. A very natural comment on this subject may be, that the commercial interests involved may always be very safely intrusted to individual enterprise. But it is quite certain that enterprise is stimulated by attrition of mind with mind, and the best developments of enterprise are elicited in discussion.

At this season of the year, when the light is bad and business inevitably dull, it is wise to consider and determine upon new effort during the coming season; and whether the American plan of discussing such details be adopted or not, we commend, as we have done before, the spirit which pervades their deliberations, in which the emphatic recognition of excellence as the means of success is always present, and a resolve to secure success by such means rather than by reduction of prices. A month or two ago we received from a provincial photographer in America an admirable example of a business circular he had just issued, and with it some of the most charming specimens of cabinet and card portraiture we have seen for some time. They are all distinguished by art feeling, and are especially well lighted: some in what is termed in the States the "Rembrandt" style, and others, still well lighted, after the more conventional fashion. The artist is Mr. F. Thorp, of Bucyrus, Ohio. Having devoted himself to producing good pictorial effects, he is satisfied that such work is worth its price, and that the discriminating

portion of the public—always the most pleasant portion to work for—will pay the price; and, accordingly, he announces his intention in the circular in question, which we reprint, although it is also issued in our YEAR-BOOK in Mr. Robinson's capital article on a similar subject. Here is the circular:—

ART NOTICE.

I would respectfully inform the patrons and admirers of art, that as soon as present orders can be completed, no more Cheap Pictures will be undertaken. That in the future I shall make only

The Highest Grade of Photographs,

and that I shall bring into requisition retouching the negative, double printing, enamelling, chromatic finishing, and all possible means for enhancing the beauty, value, and durability of my work, without regard to time, trouble, or expense, and will make for each one of my sitters the best possible picture that can be made.

The price for Card Photographs will be—

Five Dollars per Dozen, Three Dollars per Half-Dozen,

and no sitting will be made for less than half-dozen.

In thus calling your attention to the price under the new arrangement, I am aware that *pictures of a kind* are being made for much less, the limit, I believe, having been reached by a man in Chicago, who makes *twenty-four pictures for twenty-five cents*.

To all who want Good Likenesses, and are not afraid of having them shaded, I can assure a pleasing picture; and I particularly request all who never had a *good photograph* of themselves to give me a sitting. But to those who want *cheap* pictures, or who want their pictures taken *white*, I can offer no inducements, as I will no longer cater to a taste so false and meretricious, nor degrade our beautiful art by producing pictures that are in direct violation of the rules and principles of art, and that shock the taste of every cultivated mind.

Residents of town will confer a favour by making previous engagements for their sittings, and avoid the necessity of being kept waiting.—Respectfully submitted,
F. THORP.

We commend this subject generally to the earnest consideration of all engaged in portraiture, and especially to those who have been less successful than they desire, or believe they deserve.

MODIFIED METHOD OF FUMING PAPER.— SIMPLE PLAN OF COPYING PRINTS.

In his letter to our Philadelphia contemporary, Dr. Vogel describes the method of fuming sensitive paper which he has found more convenient than the common mode of fuming the pads of the pressure frame. After describing his mode of washing the paper, and then keeping it ready for use for weeks, he says: "The paper becomes sensitive as soon as it is fumed with ammonia; without ammonia the prints are very weak.

"The fuming with ammonia is certainly a very simple operation, still it requires some preparation and apparatus; a fuming box or closet is necessary, and also time. I have considered the matter over, and tried to find a way to dispense with the fuming altogether (I refer to washed paper), and I have succeeded in a very simple manner.

"I place behind the sensitive paper, in the printing frame, a piece of felt or cloth which has been on the outside covered and rubbed with carbonate of ammonia. In order to prevent the particles of the salt coming in contact with the paper, the latter is first covered with a piece of blotting paper; next comes the felt or cloth, with the ammonia side furthest removed from the negative; on the top of this the printing pad; and finally the frame is closed by the cover. The fuming process takes place in the printing frame, and the printing goes on very rapidly.

"This method is more convenient than that formerly recommended—*i. e.*, fuming of the printing pads. It is easily controlled, as we can at any time examine if enough carbonate of ammonia is left on the felt or cloth, or not; but it is particularly convenient to amateurs who wish to work with as little apparatus as possible."

Dr. Vogel then proceeds to describe a very simple method of copying prints adopted by himself and pupils, which the use of permanent sensitive paper materially facilitates. He says:—

"A piece of permanent silvered paper, a flat board, and piece of glass, a few American clothes pins, and a piece of felt, with a little carbonate of ammonia, is all that is required. I took, recently, the few articles just mentioned, in a portfolio to the University, and copied from a scientific work a plate by just placing it in front of the window.

"The print was clamped together with the sensitive paper, and exposed to the light, while I occupied my time with reading and writing. I got an exact copy of the plate—a negative, of course—in a similar manner to the one by which Mr. Walker, in Washington, obtains his negatives. As soon as the ammonia is evaporated the paper keeps tolerably well; if it is to be preserved for a longer time it should be fixed in hyposulphite of soda, and washed.

"That only albumen paper can be used for this purpose is a matter of course."

SOME RECENT APPLICATIONS OF PHOTOGRAPHY.

Two years ago Captain Jouart, of the French Imperial Guard, published a clever little book on photography applied to military surveying. The greater portion of Captain Jouart's remarks were based upon some practical results obtained by means of the Chevallier Plane-table, and went far to show the vast utility of photographic operations in connection with warfare. Unfortunately, the death of M. Chevallier brought to a close the series of experiments which had been commenced by order of the Emperor at Toulon and Vincennes; and Captain Jouart, we suppose, was not sufficiently in M. Chevallier's confidence as to have been a sharer in that inventor's knowledge, and to be in a position to continue the investigation. Among other feats which M. Chevallier professed himself able to accomplish was one which, if possible, would just now be of some use to the contending armies at Paris, and especially to the German forces. This was to regulate, in the most certain manner, by the aid of two proofs obtained with his instruments, the direction of fire against an enemy's works during the night-time, as likewise to determine the angle of reflection of the electric light, to be used in illuminating the enemy's position during its bombardment. Another task, scarcely less important—viz., to regulate the convergent fire of one or more batteries, as well during the night as during the day—Chevallier also pronounced feasible, by means of his apparatus, which was capable of furnishing, upon a horizontal plate, a ground plan of any position or landscape, together with the direction of the magnetic meridian; and it is therefore by no means impossible that he might have been able, as he said, by employing a couple of plans of this kind, taken at two different points, forming the basis of a triangle, to have directed the sighting of cañon, or angle of the reflecting mirrors, in the desired direction during night-time.

No practical application of such a method has, however, to our knowledge, been adopted, although we know for certain that at Strasburg, at Metz, and, more recently, at Mezières, photographic observations were taken for topographical purposes. The most important use of the camera during the present war has, undoubtedly, been for the transmission of intelligence from and to the French metropolis. There is no saying how far this ingenious and unerring method of conveying news in a small compass has been carried, but we are assured, by special correspondents, that micro-photography is certainly resorted to for the purpose. The method generally adopted appears to be that of reproducing a large sheet of written or printed matter upon a tiny transparent film, either of glass, mica, or some such material; and this, on reaching its destination, either by pigeon, or, not improbably, by some other two-legged messenger, may be at once amplified to its original dimensions, either by means of an enlarging

camera, or a simple microscope, the observer, in the latter case, dictating the contents of the despatch or letter to an assistant. Microscopic productions of this nature, if carried by messengers or spies through an enemy's lines, would scarcely ever be discovered, even on the most searching personal examination being instituted, and could therefore be carried by anybody, almost with impunity. One remembers, no doubt, the little toys exhibited at the last Paris Exhibition, in the shape of these micro-photographs. In some instances, as many as four of these minute pictures, together with the necessary lenses for viewing the same, were to be seen mounted at the top of a penholder, and selling for the sum of one franc, proving, beyond doubt, that facilities exist in the French capital for the plentiful production of these little marvels at a very cheap rate indeed.

Thanks, therefore, to science, in the shape of micro-photography and balloons, communication between Paris and England has been as frequent and as rapid as between this country and the Prussian head-quarters at Versailles.

Passing to more peaceful matters, we find photography has recently been playing a most important part in astronomical observations. During the Eclipse expeditions last month, which, unfortunately, have proved somewhat unsuccessful, we find that, whatever results may have been obtained, the photographic portion of the work has certainly been the most satisfactory. And there is no doubt that the art will hereafter be used for nearly every description of astronomical observation. At first the sun's disc, and the portions thereof eclipsed from time to time, was all that it was sought to register; but now we employ the photographic apparatus for demonstrating the nature of the sun's spots, and to give, indeed, their whole history—how they pass over the sun's disc from one side to the other, to reappear after a given period; how those marks change their shape, multiply, and decrease, and appear more or less brilliant from time to time; and how the distances between the spots vary from day to day. The sun's spectrum is also obtained by photography, the picture thus obtained being in many respects different to that seen by the eye, inasmuch as certain lines and colours but imperfectly rendered upon the retina are produced with much clearness and sharpness upon the sensitive film. Lastly, we have the fact of the protuberances of the sun being actually photographed in open daylight by Professor Young, of America, whose results, although no doubt at the present moment very imperfect, prove, without doubt, the feasibility of the operation; and, with better apparatus and arrangements, there is every hope that some truly serviceable pictures will be capable of being produced under these circumstances.

One more application of photography deserves mention: the aid which the art has commenced to render for purposes of scientific instruction, especially in connection with the medical profession. Preparations and objects of a minute character, usually shown in medical schools by the aid of the microscope, are now being reproduced in the form of diagrams, whose value will be very great indeed for demonstrations. As may readily be supposed, the employment of a microscope, or even half-a-dozen of such instruments, in a class room, is an exceedingly awkward, and, at the same time, unsatisfactory, means of instruction, apart from the fact that many medical preparations which it may be desired to demonstrate to the students are not always to be had just at the moment when they are required. By using, however, large photographic diagrams, obtained from objects of the most perfect character, the peculiarities which it may be desired to point out are seen at once clearly and distinctly. We believe Messrs. Robinson and Thompson, of Liverpool, whose beautiful micro-photographs attracted such general attention at the last meeting of the British Association, are at present engaged in depicting objects of this kind, interesting to the surgeon and physician, to serve as illustrations at the lectures in

the Loudon hospitals. Certain it is, that pictures taken in this way of carefully prepared specimens will be a very great boon, both to students and professors.

Such are some of the more recent applications of photography to matters of infinite importance, in which the art adds very greatly to the end attained. And thus we see that while the photographer is still making strenuous exertions, on the one hand, to earn some title to be admitted as a votary of art, he does not, in the meantime, forget his duty, in rendering assistance in matters of a scientific and technical nature.

Foreign Miscellanea.

THE *Photographische Correspondenz*, the principal Viennese paper, has passed from M. Schrank into the hands of Dr. E. Hornig, who will in future be the editor. A resolution was passed at the last meeting of the Vienna Photographic Society, to the effect that the *Correspondenz* should still be considered the official organ of that body, and have the support of the members. Dr. Hornig's contributions to photographic literature are well known, and his scientific attainments are a good guarantee of the manner in which the duties he has assumed will be fulfilled.

A critique of the London photographic exhibition has been communicated by a correspondent to one of the German journals. It is a very favourable notice, and speaks highly of the different works shown, although no comparison is made between English photographs and those produced abroad.

The Victoria card, or mount, between the sizes of a carte and a cabinet picture, which, by the way, is receiving much more attention abroad than at home, has been highly approved by the Vienna Photographic Society. In adopting it, a proposition was made to give it the designation of "Elizabeth card" by M. Fritz Luckhardt, the well-known Austrian portraitist, who has already adopted the dimensions for the bust pictures for which he is so famous.

The cameo medallion picture, of which we recently gave a description in the PHOTOGRAPHIC NEWS, is becoming a favourite *format* in Germany, and bomb-presses, for the stamping of such productions, now form one of the ordinary requisites of photography.

Exertions are being made in Austria to ensure a good show of pictures at the forthcoming International Exhibition to be opened in London next year. Applications are required to be made at once by intending exhibitors, who must specify the amount of space they intend to occupy.

M. Fritz Luckhardt has been permitted by the Empress to take the title of Imperial Photographer, in acknowledgment of the high class character of his photographic work.

It is rumoured that M. Reutlinger, whose beautiful cabinet pictures enjoy world-wide reputation, and who was obliged to leave Paris some short time before the siege, will shortly open a studio in Vienna.

A *Photographische Jahrbuch*, or year-book of photography, is announced to appear in Vienna, modelled, no doubt, upon our own little volume. The price of it is advertised at two shillings, and it will contain all information necessary for carrying on practical photography. Dr. Hornig will, it is believed, be the compiler and editor.

M. Leth has worked out a process of enamel photography, which he communicated on a recent occasion to the Vienna Society; he likewise illustrated the method by executing before the eyes of the members a perfect specimen of the process.

In the *Correspondenz* for December appears a long article by Dr. E. Hornig on the production of oxygen from various sources, bearing especially on the question of printing or enlarging by means of artificial light.

M. Baden writes to the *Photographisches Archiv* to defend his claim to having first suggested the employment of washed and fumed albuminized paper. It will be remem-

bered that M. Haugk disputed the statement of M. Baden, and hence the discussion.

A beautifully plastic and brilliant effect in photographic prints has been secured by Dr. Szekeley, who has, however, patented the method for obtaining the same. His motive for obtaining protection is for the purpose only of recovering such amount of money as his experimental researches have cost him, and he offers, therefore, to allow any one to practise the process on payment of ten florins.

From France nothing of photographic interest has been received for some time past.

PRACTICAL WORKING OF THE COFFEE PROCESS.

BY R. TUDOR WILLIAMS.

I HAVE much pleasure in forwarding the following details of the coffee process as employed by me, but I must also say that I have no new information to give—in fact, nothing but what has been many times stated by abler men than myself. I briefly state the method and formulæ I have found successful.

I clean the plates as directed by Mr. Jones, Marlborough, and coat with his tunicare, which, as I have before said, is an excellent substratum for dry collodion.

The collodion I use is either Thomas's or Rouch's; either answers admirably.

The bath is made of—

Nitrate of silver, pure	40 grains
Water, distilled	1 ounce,

iodized in the usual way, filtered, and made slightly acid with nitric acid.

Infusion of coffee (Baratti's)—

Coffee	1 ounce
Best white sugar	$\frac{1}{4}$ "
Boiling water	10 ounces

When cold, filter for use. I do not like to use this infusion when it is more than a day old. The most convenient way of using this preservative is in a dipping-bath.

The exposure, I have found, in a good light, to vary from four to six times more than that required for wet collodion.

I use an *alkaline developer* (the one recommended by M. Carey Lea, in his most excellent book) made as follows:—In bottle No. 1 make a *saturated* solution of carbonate of ammonia in *tepid* water; if the water is too hot it will decompose the carbonate of ammonia.

In bottle No. 2—

Pyrogallie acid	300 grains
Alcohol	5 ounces

In bottle No. 3—

Bromide of potassium	$\frac{1}{2}$ ounce
Water, distilled	20 ounces

All these solutions should be filtered and labelled; they all keep well.

I make this developer of different strengths, according to light, subject, &c.; but, perhaps, as a general rule, the following formula will answer best:—

Water, distilled	6 ounces
Saturated solution of carbonate ammonia (bottle No. 1)	$\frac{1}{2}$ drachm
Alcoholic solution of pyro (bottle No. 2)	$\frac{1}{2}$ "
Solution of bromide of potassium (bottle No. 3)	$\frac{1}{2}$ "

I recommend sufficient of this developer to be made (just before use) to admit of its being employed in a flat white dish. Should the image appear very slowly, half a drachm from each of the bottles Nos. 1 and 2, but not from No. 3; if necessary twice this quantity may be used; or should the image, on the other hand, develop too rapidly, immediately take the plate out of the solution, and add one

drachm from bottle No. 3 (solution of bromide of potassium); this, to a certain extent, will stop over-action of light on the plate got in the camera.

As soon as all details are well out by reflected light, thoroughly wash away this developer.

This phantom image—for it is but a phantom—is now to be intensified in the usual way with acid, pyro, and silver; by this means printing strength is rapidly obtained.

The three most important points in the coffee process, as in most other dry processes are—1st. Carefully washing of the plate after it leaves the nitrate bath: the means I think most effective is to use a dipping-bath for this purpose, and to wash until the surface of the plate is quite smooth (this water may be used for six plates), then transfer it to a dish of common soft water, which water must be changed three or four times (by this means the plate can be rapidly washed), finally flush with distilled water, and apply the preservative, which is most conveniently done by a dipping-bath. The reason I advocate thorough washing is, that I believe free nitrate of silver in the film is not necessary to the formation of the latent image; therefore the more perfectly it is removed the longer the plate will keep, and the more perfect will be the result in the end.

2nd. The absolute necessity of perfect drying, for I believe that many dozens of otherwise perfect plates are completely spoiled by imperfect drying. The best plan I know is that recommended by Mr. Carey Lea, viz., round the inside of the drying-box arrange tumbler-glasses, one for each plate to be dried, and when the last is set on its tumbler, place a dish in the middle containing about one pound of sulphuric acid, but the dish should be large enough to hold twice the quantity. The same acid may be used three or even four times. I generally prepare my plates in the evening, and they are always quite dry the next morning.

3rd. That an alkaline developer should be used; it has so many advantages over the old methods: the exposure is much shortened, more even development is ensured, the plates give better results after long keeping, and there is greater freedom from stains.

I sincerely trust that my hints found in the above may prove of use to some of your readers.

DISSOLVING VIEWS WITH ONE LANTERN.

BY J. MARTIN.

I SEE that the proposed method of Mr. Powell for producing dissolving effects with one lantern has begot him some smart raps from the pens of Mr. B. Jones and "Silvester." Although Mr. Powell displayed a want of caution, still I think neither of his critics is justified in taxing him with untruthfulness. His supposed invention satisfied himself, and he hastened to offer freely to your readers what he considered a valuable idea. Does he deserve insult for this? I think not. Let him exercise his ingenuity in other directions, and I for one shall be happy to congratulate him upon the production of any useful addition or improvement, and render him any assistance through your pages.

When an idea is put before the public from an obscure source it should be taken for what it is worth, and weighed by reason and experience; and those who elect to try the experiment ought not to vilify the author should it turn out a failure, but blame their own rashness for rushing into expense without due consideration; and if actuated by a mean desire for cheapness at the expense of convenience and efficacy, their losses are well deserved.

I fear that parsimony has been the cause of many of the childish subterfuges proposed to the photographic public. I have read that it is possible to bottle up light. Suppose some one tries to extract sunbeams from cucumbers! Should he succeed, he would be the greatest benefactor to photography ever known, as its professors would then be independent of all expensive artificial sources of light—a

benefit which, in this dull weather, would be beyond appreciation. But, as a caution, the remedy must not prove more costly than the evil, as it did with the inventor who, to save human labour, built a steam engine to cut cabbages—*verbum sap!*

I feel sure that it would be more satisfactory to the public, and more creditable to the common sense of inventors, if the titles of their productions, instead of being, as they generally are, composed of a conglomeration of syllables from words in an obsolete language, were as suggestive of their purposes as that of the dissolving view lanterns. The child must be young indeed who does not comprehend that the verb to dissolve means to melt away. In the English language there are many synonyms. In this instance it is not disintegration that is to be understood, but a fading or being gradually lost to sight. This effect may be produced with a single lantern by slowly passing a dagger-shaped piece of dark-coloured glass over its nozzle; and, when it entirely covers it, allow it to rest there by a properly shaped handle until the slides have been shifted, then slowly withdraw it. This device does away with the bold white disc of light which is seen when no picture is in the holder, but leaves the audience in some darkness in the interim.

This effect is more properly obscuration than dissolving, which not only requires that one picture should be fading away, but also that another shall be growing visible in its place, and that they shall be so magically intermixed that the eyes of the spectators do not perceive where the one ends or the other begins. Two pictures passing across each other in juxtaposition will not effect this; they must, on the contrary, be placed separately, each having its own light and lenses, and be subject to the influence of a properly constructed dissolver, which latter must be placed without the focus of the lenses, so that the effect may be soft and weird-like. There are various forms of dissolvers—in fact, most manufacturers have some special form peculiar to themselves—but the purpose in all is the same, but their completeness and efficiency vary greatly. The simplest form is that of the fan; but a dissolver, to be really of service, must be so constructed as to allow the two pictures—or, rather, the picture and its effect—to be seen at the same time when required, as, for instance, in showing the slide of the "Soldier's Dream," &c. Of all that I have tried, I prefer one invented by a clever friend: it is of simple construction, and can be applied to any pair of lanterns. I fear to enter into description, as without drawings it might prove unintelligible, and, I fear, would require too much space at present.

106, High Street, Ilfracombe.

INTENSIFYING NEGATIVES.

BY ELBERT ANDERSON.

MR. ANDERSON'S last conversation with his pupil, in our Philadelphia contemporary, is on the subject of "strengthening" negatives, a practice which, as a rule, he does not approve. Addressing his pupil, he asks—

Why do you "strengthen," or, rather, what is the effect of "strengthening," as you call it?

Marshall, the Pupil. Why, it makes the negative stronger or more intense when it's too thin; don't it?

A. No, and yes. It makes certain negatives only stronger.

M. I thought it made all negatives stronger.

A. No, Marshall, you are wrong, though it is very natural for you to think so. It does not strengthen all negatives, as its name implies. Certain negatives undoubtedly require it, but in portrait photography most of these thin and beautiful negatives are totally ruined by any attempt to strengthen them. There is a certain class of photographers who strengthen every negative they make; and if you ask them why, they look down, and confused, and say because—well, because they always do it. A capital reason (!), though somewhat unsatisfactory.

M. Will you please enlighten me on this subject?

A. In copying engravings, wood-cuts, cards, printed matter, &c.—in fact, any matter that is simply black and white—in order to make the contrast brilliant it is essential that the white of the paper be kept clear, and the negative must, in consequence, be very intense—*i. e.*, opaque; a first strengthening with pyro before fixing, and a second application of mercury afterwards, may, therefore, become imperative. Now tell me exactly, what takes place when we strengthen a negative?

M. Yes; it makes an additional deposit of silver all over the negative, thus rendering it more intense.

A. Now you see that if you think so, it is perfectly natural for you to strengthen a weak negative; but the fact of it is, that it does nothing of the sort.

M. Well, then, I might just as well hang up the fiddle and the bow. Please tell me what it does do.

A. I will, by the aid of some diagrams which almost explain themselves. Let A B, fig. 1, represent your glass; C D, the

coating of iodized and sensitized collodion; and you are about to copy an engraving, printed matter, or anything that is simply black and white. You have now poured on your developer, which has deposited only on the lights—*i. e.*, what will represent the white of the paper in the proof, and is seen at E F—whilst that part representing the blacks of the printed matter will receive no deposit, and is represented by the clear space between F and D.

M. Just so.

A. Now, as most probably will be the case, the deposit of silver, E F, will not be sufficiently opaque to entirely obstruct the light during printing; and in order to remedy this, we strengthen it by an additional deposit, G H.

M. Well, that's exactly what I said; but you said it did nothing of the sort.

A. Gently, gently: you said it made an additional deposit of silver all over the negative, whereas this deposit has taken place only on the lights, proportional to the first deposit; and thereby hangs a tale.

M. Please put a head on it.

A. Now listen to me. In the first instance, as the negative represents only black and white, the deposit is equal in thickness on all the lights.

M. Surely.

A. Consequently, the additional deposit is also equal in thickness. So far, so good. But with a portrait negative the case is wholly different.

M. How so?

A. Let A B, fig. 2, represent the glass, C D the collodion

film, but, in this case, the deposit of silver is represented at E F, not as a flat surface of uniform thickness, but with an infinite gradation of light and shade, the highest lights being represented at E, gradually tapering down to F, and the perfect shadows by F D, or the clear film. Now what is the effect of the strengthening?

M. Why, an additional deposit, represented at G H.

A. And that's just where you are wrong. The additional deposit, as I said before, is only in proportion to the first deposit, and can be at once understood by a glance at fig. 3, showing

the additional deposit follows the principle of the first, and tapers away to the clear film, where, as you say, no deposit takes place. Now, then, when you have a good negative, with the proper contrast of light and shade, let it be as thin as gauze. Any attempt to strengthen it tends at once to destroy the proper balance between the lights and shades, and the nature of the negative is changed, or, in plain terms, ruined. But if you have a negative that is flat and thin, and in which the contrasts are insufficient, strengthen that negative, and you will increase the brilliancy; but, better still, don't make that

kind of negative. And now for one of my standard rules: "All the chemicals and skill in the world will fail to produce a really good negative if the subject is not properly lighted in the first place."

BICHLORIDE OF PLATINUM FOR INTENSIFYING.

BY T. W. WILKINSON.

THERE has always been a want felt for an intensifier for negatives that have been exposed and developed to a nicety, all details in the shadows quite distinct, the high lights and half tones full of gradation, but just lacking density sufficient to give a vigorous print. Pyrogallic acid and silver, or iron and silver, if used before fixing, are apt to clog up the half tones and spoil the negative; if used after fixing, very great care is requisite, or red fog speedily ruins the negative. Pyro also must be used in the dark room, so adding another chance of failure. Iron certainly may be used in white light, but if the negative be not perfectly washed, red fog quickly supervenes. To obviate all these difficulties an intensifier has been wanted that, without increasing the thickness of the deposit, would give to both high lights and shadows a non-actinic colour that would render the negative dense enough for printing without clogging up the delicate half tones. Mr. Simpson's bichloride of platinum intensifier—

Bichloride of platinum	4 grains
Water	1 ounce

neutralized with carbonate of soda and rendered acid with nitric acid—completely fulfils these conditions, working well and quickly. The colour of the deposit being the same as when iron or pyro is used, makes it easy to use; and the operation of intensifying being conducted in white light, the proper amount of intensity is obtained with more certainty than when operating behind the yellow window of a dark room.

IMPROVEMENTS IN THE MONCKHOVEN ENLARGING APPARATUS.

At the November meeting of the Vienna Photographic Society, Dr. Van Monckhoven announced the progress he has recently made towards perfecting the lighting arrangements of his oxy-hydrogen apparatus. His communication was as follows:—

"A year has now passed since I had the honour of reading a paper before you on a new artificial method of lighting, especially suited for enlarging purposes. I then recommended the use of titanate acid mixed with magnesia, pressed into pillars by means of the hydraulic press; of this material I have here several samples, but its costly nature has prevented its regular employment.

You will remember, perhaps, that I employed, in the first place, instead of lime, which is used in the Drummond light, parallel pipes of pressed carbonate of magnesia, and afterwards some of dense dolomite taken from the Kaiserstuhl mountain in the Grand Duchy of Baden. Of these I produce a series of specimens, and, when taken in the hand, there will be found to be a material difference between the artificial and natural compounds. It will, moreover, be remarked that the new specimens are light and porous, while the others are hard and dense.

"The lighter material presents a serious difficulty from the fact that it is very easily burnt, or, in other words, is rendered much denser on the influence of a high temperature. This experiment I will conduct in your presence by allowing the oxy-hydrogen flame to act at the same time upon a porous and dense magnesia column. Although it will be perceived that the former yields, in the first instance, a more brilliant light than the heavier one, this advantage is only momentary, and it becomes necessary very soon to alter the

focus of the enlarging apparatus, a difficulty required to be overcome every quarter of an hour; moreover, this modification of the flame, if not very nicely regulated, will have an injurious influence upon the sharpness of the enlargement.

"For this reason it would appear to be best to prepare artificially the material of a dense nature, and in the following manner:—

"Two kilogrammes of English caustic magnesia are mixed with one kilogramme of carbonate of magnesia (magnesia alba) in lumps, together with half a litre of water, and kneaded with the hand into a dense and uniform dough; in this condition it is put into a shallow box and pressed in a suitable screw press—as, for instance, a letter copying press—and then cut up into suitable pieces and dried by placing in an oven for a few days, and afterwards subjecting them for about half an hour to a red-hot heat.

"The pieces of magnesia which I have now with me have been prepared in this manner, and are, as you will see, perfectly uniform, and consumed but slowly; they are, however, burnt away by degrees, and it would be much better were they preserved intact in the flame of the oxy-hydrogen lamp. This last condition I have recently been able to fulfil.

"I thought that the admixture of a body capable of withstanding fire to the carbonate of magnesia would secure greater protection to the same, and in this hope I applied silicic acid, chromic acid, alumina, and lime. The last named substance gave me the most favourable results, especially when there is a well-pronounced trace of oxide of iron therein.

"In nature we find in many places whole mountains made up of carbonate of lime and carbonate of magnesia, containing also, as a rule, traces of oxide of iron, silicic acid, and other materials; even in the environs of Vienna geologic formations of this description are to be met with. These dolomites I now employ in a burnt condition; only the porous quality of this material should be selected which does not appear too heavy when calcined. The fire of the oxy-hydrogen flame penetrates this compound without consuming it too rapidly.

"We have, it is true, a somewhat less amount of chemical rays in our light than previously, but then, on the other hand, we can depend more implicitly upon its permanence, so that after the apparatus has once been set in working order it is no longer necessary to keep a continual watch over its action. The progress thus made will, moreover, so simplify the working of the instrument that it will be preferred to one requiring the aid of a heliostatic arrangement; the light is permanent, brilliant, and quiet, as I demonstrated last year, and the apparatus is so constructed that no fear of danger need be entertained.

"While occupying your attention, gentlemen, I have placed a sheet of paper, prepared with arrowroot and chloride of sodium in the well-known manner, in the fields of one of my enlarging lamps. The sheet measures 55 by 90 centimetres (22 by 36 inches), and the negative employed is a small bust portrait of carte-de-visite size. I purposely chose an enlargement of notable dimensions in order to render at once apparent the progress that has recently been made; the process has now proceeded for less than half an hour, and the image, which is now well defined, will be developed and fixed in your presence, so that you may perceive that the operations are as easily conducted as with collodion, and the tone of the prints as pleasing almost as that of albuminized paper.

"I may therefore flatter myself with having solved a problem with which photographers have been busy for some time, viz., the production of enlargements in the winter time independently of sunlight. The light is easy and simple of production, very permanent, unbeset with difficulties, and capable of furnishing positive prints in a safe and efficient manner.

PHOTOGRAPHIC PROCESSES OF THE PRESENT DAY.*

The last two or three years will certainly mark an era in photography, for not only have several novel and important printing methods been discovered during that period, but other processes of less recent origin have of late been so elaborated and improved as to have become at the present moment practical and easy of manipulation. All of these are, without exception, based upon the action of light upon the bichromates of potash and ammonia; in no single case is the use of a silver salt involved—the agent employed for securing the photographic image in ordinary paper printing—and this is, in truth, a point whose value cannot be too greatly insisted on; for the silver print, be it washed and freed as thoroughly as possible from any deleterious bodies, will always suffer, more or less, from attacks of an impure atmosphere, the delicate metallic film of which the image consists being peculiarly liable to change, from the sulphur compounds and other impurities not unfrequently contained in the air we breathe. And even those silver pictures which do not at first show actual traces of fading or discolouration, will very soon be found, on careful examination, to have parted with some of their original brilliancy, and to lack the pristine freshness which always characterises newly-produced albuminized prints.

It is a great step onwards, then, to have at our disposal practical processes in which the employment of silver may be altogether dispensed with, by the substitution of another material of a more permanent character, either in the form of a chromium compound, or, what is better still, in the shape of gelatinous or greasy ink; and so clear and promising does the photographic horizon appear just now in this direction, as to leave little ground for doubting that before long the practice of printing in silver will be generally abandoned.

All recent printing processes rest, as we have before said, on the action of light upon the bichromates. And here we would parenthetically refer to a simple and familiar experiment which will help very materially to simplify our subsequent remarks. The well-known plan pursued by school boys for printing fern leaves and other objects by the aid of the sun, will readily be called to mind by many of us, and this simple manipulation it is that forms the groundwork of the whole series of inventions before us. A sheet of ordinary paper, which has, of course, been sized, or, in other words, received a thin coating of gelatine, is rubbed over with a solution of bichromate of potash; the latter, as we know, when mixed with any organic body, renders the same sensitive to light, and the sizing or gelatine upon the paper becomes in this way endowed with excitable properties. Having been dried in the dark, our sheet of paper is next placed in the sun with the fern leaf, or other object to be copied, pressed down upon it, and the light acting upon all such portions of the sheet as are not covered up, browns the gelatine there, and renders it insoluble; the sizing underneath the leaf, and screened, therefore, from the light, escapes this reaction, and remains soluble, and this, on the printing being completed, and the paper washed in water, is at once dissolved away, there remaining a white image of the leaf upon a brown ground composed of bichromated gelatine rendered insoluble by the sun's rays. This experiment may be regarded as the key to the whole question of photographic printing, and, by bearing it in mind, the reader will have no difficulty in at once comprehending the various inventions of the kind just now being made public.

The first method claiming our attention is the so-called carbon process. Photographic printing of this nature in one form or another has been carried on probably for upwards of fifteen years; but in its experimental stage the mediocre character of the results furnished by it were such as to deprive the system of any material support from

* *Nature.*

photographers, and until, in fact, Mr. J. W. Swan, of Newcastle, made known his method, no easy or reliable *modus operandi* can be said to have existed. The plan followed by Mr. Swan was to prepare a warm solution of gelatine and bichromate of potash mixed with some finely divided pigments—such, for instance, as Indian ink—and apply this mixture in the form of a coating to a sheet of paper, so that when dry, the tissue, as it is called, assumed the form of a thin black cake with a paper backing. This sensitive tissue was placed under a negative to print in the ordinary manner, the light penetrating in parts to a greater or less degree, and thereby rendering the surface partially insoluble. On removing the tissue from the printing frame, it might, if it were desired, be forthwith washed to remove the soluble portions (as in the case of the fern leaf experiment), but by so doing the picture would be hard and deficient in detail, and, therefore, a slight modification is here instituted. Instead of washing away from the face of the tissue, the operation is pursued from the back, the film being, in the first place, cemented face downwards upon a sheet of india rubber, and in this condition put into a tank of warm water. The original paper backing of the tissue is in this way at once washed off, as is also every part of the gelatine mixture not rendered insoluble, which latter, constituting the image itself, remains attached to the india-rubber sheet before mentioned. The picture is now sufficiently developed, and, indeed, quite perfect, except that it is reversed to our view, for we are looking at it, it must be remembered, from the back; this defect is, however, easily remedied by attaching to the image another sheet of paper by means of gum or gelatine, and then dissolving off the india-rubber facing by means of benzole or turpentine, when the finished image is obtained resting upon a support of white paper. The object of washing the carbon tissue from the reverse side, and not from the front or surface exposed to the sun, is to secure the finer details in the picture by fixing at once to a basis such portions of the tissue as may have been but very slightly acted upon, and thus prevent them from being ruthlessly washed away when placed in warm water.

The actual composition of pictures produced in this manner consists of gelatine, pigment, and a stable chromium compound, the gelatine being in a fixed or tanned condition, by a subsequent immersion of the prints in a solution of alum, and thus there is every reason to believe in the permanent character of such prints. A more simple and ready method of carbon printing has been lately invented by Mr. Johnson, and termed the Autotype process, but the principles involved therein are nearly the same.

Passing from printing in permanent pigments—in which, as in silver printing, the aid of light is necessary for the production of each separate picture—we come next to photo-mechanical methods. Of these there may be said to be two kinds, partaking of the nature of lithographic and engraving methods. Of the first description we may mention three modes of working, all of which are capable of yielding very creditable specimens of printing: these are Albertype, the Lichtdruck process, and Edwards's collographic method. The three inventions, which differ from each other and from minor plans of a similar nature only in a few details, are all based on the same principles. A sheet of patent plate glass is, in the first place, coated with a thick solution of bichromate of potash and gelatine; this film, on drying, is placed face downwards upon a sheet of black paper in the sun, and in this way the light rays penetrate the glass and act upon the sensitive compounds adherent to its under side. The bi-chromated gelatine becomes insoluble and firmly cemented to the glass, except on the exterior surface, for the black paper upon which this has rested absorbs the rays, and leaves the outer film of gelatine still in a soluble condition. A second coating of the sensitive gelatine mixture is now applied to the former one, to which it adheres perfectly, from the fact of the first surface being unchanged, and upon the second coating an image is printed by means of a

negative in the ordinary manner. After printing, the progress of which, by-the-by, may be watched through the glass, instead of washing the surface and dissolving out all the soluble parts, a sponge dipped in cold water is simply rubbed over it, the moisture being absorbed by the gelatine where it has not been acted upon by light, and is capable, therefore, of swelling out; those portions of the film, on the other hand, which have been rendered quite insoluble and hard, are unable to take up any water whatever, and remain untouched, therefore, by the action of the sponge; while other parts again, slightly exposed to light, absorb water just to that degree to which they have remained soluble. In this condition an inked roller is passed over the surface, in the same manner precisely as in lithography, the greasy ink adhering to all the insoluble surfaces (where no water is), and to the other parts in a greater or less degree, according to the amount of water present in those places. Thus the gelatinized glass is treated in every sense like a lithographic stone, being moistened, inked, and pressed in the same manner; the resulting print, however, is generally finer than that obtained in ordinary lithography, as the graining of a stone surface is always somewhat coarse, while in the present instance the breaking up of the ink by the minute pores of the gelatine impregnated with moisture is of an exceedingly fine character. Many thousand prints may be pulled off a printing block of this kind before it is destroyed, as the double layer of gelatine imparts a yielding nature to the plate which is not easily damaged; in Germany, in England, and also, we believe, in America, this process of photographic printing is extensively practised.

But by far the most important of all methods yet discovered is the Woodbury engraving process. So simple, and, at the same, so perfect in its work, a casual observer cannot fail at once to appreciate its value. A thin sheet of gelatine is sensitized by impregnation with bichromate solution, and exposed to light under a negative; subsequent immersion in warm water removes the soluble portions from the surface, and we have then a thin gelatine plate upon which the image is represented, more or less, in relief. This matrix, as it is called, is hardened by treatment with alum, and placed when dry in a hydraulic press, in contact with a plate of type metal. Subjected to considerable pressure, the metal plate takes the impression of the relief, and thus becomes in every sense an engraved plate, in which the darkest shadows are represented by the deepest hollows, the half-tones by slight undulations, while in the high lights there is no depression at all. The printing off of copies from this engraved plate is very ingeniously contrived. A little pool of transparent gelatinous ink is poured upon a sheet of white paper, and the metal plate is brought down upon the same with some pressure; all superfluous ink is at once pressed out, and after a pause of a few seconds to allow the warm ink to cool and to become set, the plate is again raised, and a beautifully shaded print is the result, in which the shadows and half-tones are formed by layers of ink of different thicknesses; for inasmuch as the ink is of a transparent character, and there is more or less of it deposited upon the paper according to the depths of the hollows in the engraved plate, so the half-tones are rendered with perfect gradation and fidelity, while in the high lights, almost all the ink having been pressed away and removed, there remains nothing but the white paper which forms the basis of the print.

By printing at once from many plates (for a gelatine matrix will yield several dozen of them), photographs may be printed at the rate of some thousands daily, without, of course, the assistance of light in any way. Moreover, the productions are of so perfect and delicate a nature as to be confounded actually with silver prints, being, at the same time, absolutely permanent. We are glad to say that this method is also being worked practically and extensively in this country, as also in France and America, and will, without doubt, be the process of the future; for it is indeed

the only mechanical process by means of which photographs may be rapidly produced, possessing the same degree of excellence as the beautiful, but, alas! too fleeting, albuminized pictures.

ON VARIOUS PHOTOGRAPHIC SUBJECTS.

BY M. CAREY LEA.*

I.—COLLODIO-BROMIDE DRY PLATES.

DURING two or three years past I have expended a very large amount of time and trouble in testing the effects of a very wide range of substances as preservatives for dry plates, especially of collodio-bromide dry plates. I found many substances giving excellent results.

Litmus I have already spoken of. It gives very fine, soft negatives, yielding pleasant and harmonious prints. The prints of mine which were exhibited at the Cleveland exhibition were all from plates prepared with this preservative. I found, however, by use and familiarity with the process, that the invisible image lost strength more rapidly on litmus plates than on those prepared with other preservatives. This cause, and the discovery of other modes of preparation free from this objection and more sensitive, have led me to give up litmus.

Cloves.—I mentioned some time back that a decoction of clove-heads, made with hot water, and filtered after standing a day with the cloves, gave excellent results: clean, bright negatives—less sensitive, however, than—

Flavin.—This substance gives very sensitive plates, more sensitive than either tannin or litmus. (Flavin is a dye-stuff prepared from oak-bark. It is, by some writers, considered to consist chiefly of quercitrin, by others of quercetin. This last is a decomposition-product of the former. Quercitrin, when heated, splits up into quercetin and a saccharoid body. From my observations I should say that flavin consists chiefly of quercitrin, not of quercetin). But the use of flavin is liable to a very curious objection. If the sky be much over-exposed it becomes honeycombed with curious lines, resembling a sort of mosaic. This took place, at least, with the pyroxyline which I use. Perhaps with a collodion exactly suitable this might have been otherwise. This preservative should be used in conjunction with gum and sugar—ten or twelve grains each of gum and of sugar to the ounce. The same with—

Carmin-Sulphate of Lime.—I now come to the most sensitive and best of all the preservatives that I have been able to find. It is prepared by treating cochineal insects with fuming sulphuric acid, diluting and neutralizing with lime. The details are as follows:—

Grind up one and a-half ounces of good, clean cochineal in a mortar with one fluid ounce of fuming sulphuric acid. As the paste becomes thick, add gradually more acid until in all two fluid ounces have been added. When well mixed up, transfer into a clean, dry, wide-mouthed vial; wipe the inside of the neck, cork, and set in a vessel of hot water; set aside for a week, then stir well up with water, add slaked lime till the mixture turns red litmus paper blue; throw on a filter, and add water until the filtrate fills a half-gallon bottle (eighty ounces is the usual contents of what are sold as half-gallon bottles); add a quarter of an ounce of carbolic acid.

The amount thus obtained will last even an active and energetic worker for a very long time. To use it and prepare a preservative bath for whole-size plates, take—

Above solution	$\frac{3}{4}$ ounce
Water	7 ounces
Gum, sugar, each	80 grains

Plates prepared with this preservative are about twice as sensitive as those made with tannin, gum, and sugar. They differ from all other collodio-bromide plates in this: that in all others the image is of a brown colour. In plates prepared after the above formula there is not a trace of

brown; the plates are pure grey-black. I have never before seen this shade in dry plates: they print softly and well, with no tendency to harshness.

Although carmine is not supposed to be one of the substances capable of forming a copulated compound with sulphuric acid, yet it appears most probable that it does. The above process yields abundance of an organic lime salt, very distinguishable from sulphate of lime by its ready solubility in water. And this ready solubility of the lime salt is generally a characteristic of copulated sulphuric acids, and furnishes an easy mode of distinguishing them from the almost insoluble ordinary sulphate of lime.

Sensitive Mixture.—I find with these very sensitive preparations that the collodio-bromide mixture may be made much thinner, and in this condition it is easier to make a smooth plate. I recommend:—

Ether, concentrated	8 ounces
Alcohol, 95 p. c., pure	4 "
Ordinary crystallized bromide of cadmium (Cd. Br. + 4HO)	1 drachm
Bromide of ammonium	12 grains
Intense pyroxyline...	84 "

This should be kept at least a month in a warm light room. When wanted for use, take out such portion as may be wanted, and sensitize in hot weather with nine grains nitrate of silver, in cool or cold weather with ten grains. This still leaves a large excess of nitrate of silver, as the exact equivalent of the bromides in an ounce of the collodion is between six and seven grains of nitrate of silver. Dissolve this nitrate, which should be in fine powder, in 95 p. c. alcohol, allowing a quarter-ounce to each nine or ten grains as the case may be. Add, at first, about half the alcohol, boil gently and carefully over a gas flame. As soon as it boils, remove and agitate carefully. When the alcohol seems pretty well saturated, pour off into the collodion. Next add more alcohol, and repeat till all is got in. This is the only mode of operating which actually gets the nitrate of silver into solution; other methods leave a considerable amount undissolved, and, therefore, comparatively useless. One good shaking after the addition is sufficient. The mixture should stand eight to twelve hours before being used. It is safest not to keep it longer than twelve hours.

Before, however, adding the nitrate, it is necessary to acidify the collodion with aqua regia. The use of nitrate of silver in excess (that is, beyond what is necessary for the complete decomposition of the bromides), and the acidification, form the distinctive features of my method of working the collodio-bromide process. They cannot be separated, but supplement each other. The use of nitrate of silver in excess gives great sensitiveness, but if the acid were not present, the plates would fog. It is important to bear this fact clearly in mind: if the aqua regia is forgotten, every plate must be expected to fog. The proper proportion of aqua regia is two drops to the ounce of collodion.

With a good light, these plates are as sensitive as wet collodion plates. The development is, of course, by the alkaline method.

Keeping Qualities.—The keeping qualities of these plates are very satisfactory. On November 25th I developed a plate which had been made on the 10th August, and was, therefore, three and a-half months old. It did not appear to have lost in sensitiveness, and was clean and clear of fog.

II.—DUST.

I believe that dust floating in the atmosphere occasions more annoyance to the photographer than is often realized; that is, that troubles really arising from dust are often attributed to other causes—for example, to imperfect filtering. A glass plate is thoroughly cleaned, well brushed with a flat camel's-hair brush, and then coated. Although the collodion was supposed to be all right, yet as the coat sets, it shows somewhere a little knot or warty place,

* Philadelphia Photographer.

perhaps more than one. Now, that this may have arisen from imperfect filtration is certain, but it much more often results from motes or filaments of dust settling on the plate in the moments that intervene between brushing off and coating. In a weak light of the dark room it is difficult to see dust in the atmosphere; even in a room ordinarily lighted it is not easy, but if a glass plate be held in bright sunshine, and be then brushed and coated, the agency of the dust becomes at once apparent.

So pinholes are sometimes caused by dust in the camera setting on the plate. This effect is more generally understood than the former.

In varnishing negatives it constantly happens that, although the negative may have been brushed off immediately before applying the varnish, and though the varnish may be perfectly bright, nevertheless, the coat, as it dries, shows irregularities. These, when examined with a lens, will generally be found due to a little filament of wool coiled up in them, and arising from the wear and friction of clothes or carpets.

ANOTHER SIMPLE STILL.

MR. A. ST. CLAIR describes, in our Philadelphia contemporary, another very simple still, as follows:—

"The distilling apparatus consists of a common tea-kettle, with the spout removed, and two tin tubes, three inches long and an inch in diameter, inserted, one in the top, near the edge, the other in the lid, which is soldered tight. The condenser is a sheet of tin, bent to a little over half a circle, with end-pieces soldered in, making a trough twenty inches long and five and a half deep; a pipe, half an inch long and half an inch in diameter, is inserted through the bottom at one end, to permit the water to be drawn off when over-heated; half an inch from the bottom a tin pipe, an inch in diameter, passes entirely through it, projecting six inches at each end; at the same end with the escape-pipe in the bottom, an elbow tapering to a point is attached, while another elbow connects it with the tube in the top of the kettle; a wire is inserted in the edge of the trough, diagonally across it, to suspend it by. To use it, I get my kettle boiling, then attach the condenser, and suspend it to the cross-piece of a head-rest, so that the pipe has a slight incline, to cause the condensed steam to flow towards the discharge-point; put a pail of cold water into the trough, and the distilling commences immediately; a bottle set to catch the water, as it distils, completes the operation.

"The cost of the kettle and condenser is two dollars.

"If more than a kettleful of water is required, I replenish by adding hot water through the tube in the lid, which is kept corked during distilling; if the water in the trough becomes too hot, withdraw the stopper from the tube in the bottom, and when empty, fill up with cold water.

"I seldom need to do this, as the water in the trough is always cool enough to condense the steam; and if the distilled water is not hot enough to break the bottle, it is all right."

Correspondence.

COMBINATION PRINTING FRAMES.

DEAR SIR,—Allow me to state that the registering frames for combination printing, described by Col. Stuart Wortley in your last number, are an infringement of my patent, and are fully described in my specification, dated 10th May, 1870, by which it will be seen that any method of combination printing in which the negatives and the sensitive paper or tissue are fixed to interchangeable frames or boards which are made to fit or register to each other is included in my patent.—I am, dear sir, yours truly,

B. J. EDWARDS.

Hackney, January 6th, 1871.

COMBINATION PRINTING-FRAMES.

Headquarters of General Faidherbe's Army of the North.

Boisieux, January 9th, 1871.

SIR,—Being here to arrange for the distribution of the funds collected by the exhibition and sale of my photographs, I can only give a short answer to Mr. Edwards's statement, an extract from which has been sent to me. (I believe it is in the News, but, anyhow, I shall be glad if you will print this.)

My plan for registering printing-frames was ready before I had overheard of Mr. Edwards's. It is based on Mr. H. P. Robinson's printing-frame for opal glass, of which Mr. Edwards's is a direct copy, and which prevents Mr. Edwards's patent being tenable. The only change is the ordinary drawing board on which the paper is stretched, and which was used in *Boothlytype* for stretching, collodionizing, and printing paper on, and is no novelty.

When Mr. Edwards's frame was announced, I was about having some large frames made on my model; but, thinking his would be less cumbersome, and cheaper than my model, I asked him to visit me. He did so, and then quoted prices which were far higher than my own models could be made for (indeed, unreasonably dear); so, as there was no compensating advantage, I had my own made.

No negotiation whatever for a licence took place, nor was a word on the subject mentioned.

Finally, I do not fear his threats of law, knowing how thoroughly Mr. Robinson's frame anticipated his.—Yours,

H. STUART WORTLEY, Lt.-Col.

PS.—Anyone seeing my frames and Mr. Edwards's will see how different they are in design, though, of course, their common origin is traceable. The fact remains that, as I propose, a few shillings will convert a frame of any size into a perfect registering one.

EXPRESSION IN SITTERS.

SIR,—In photography great difficulty is experienced, both by the photographer and the sitters, through their becoming too serious and stiff. I think that this might be overcome by placing a mirror at the point at which the persons are directed to look whilst being taken, by which they could see themselves, and thereby remedy many defects, both in countenance and figure.

If you think this suggestion worthy of notice you would oblige by giving it a place in your columns.—Yours obediently,
Gateshead, January 7th, 1871. COLUMBA.

[The suggestion of our correspondent has been tried, and found unsuccessful. Sitters seeing themselves in the glass are apt to grimace or to change their expressions during the time of sitting, or even to alter the position of the hand, which suddenly strikes as unsatisfactory. The great object to be obtained is an easy, unaffected, disengaged aspect, whilst nothing would so much tend to produce an effect of self-consciousness in the sitter as looking at himself in the glass.—ED.]

M. ADAM-SALOMON'S MODE OF LIGHTING.

SIR,—Will any of your numerous readers oblige by giving me their practical experience on their success with Adam-Salomon's new background, as I have to make extensive alterations in a studio I have just purchased, which either necessitate my using an alcove background, or entirely rebuilding, as the light is only obtainable from east and west, consequently the room is flooded with diffused light.

What I wish to be informed is this: Will the amount of light coming into the room between the sitter and lens cause want of brilliancy as it does with present method of lighting, or am I to understand that any shaped studio will answer?

I do not wish to raise obstacles against this admirable background, but feel reluctant to make extensive alterations without hearing the *pros* and *cons* of my professional brethren.—I am, sir, yours, &c., S. V. W.

January 9th, 1871.

[Loss of brilliancy is caused by diffused—or, rather, reflected—light entering the camera, not by light existing between the sitter and the lens. If the latter be properly protected from reflected light by a projecting hood, the light in the room will not affect the picture. If the atmosphere were filled with vapour or similar body, and this were illuminated by light in the room, the brilliancy of the picture would be affected; this is an abnormal condition, not important to consider.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.

The usual monthly meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, January 10th, Mr. J. GLAISHER, F.S.A., in the chair.

The minutes of a previous meeting having been read and confirmed,

The CHAIRMAN, referring to the death of the late Rev. J. B. Reade, paid a high tribute to his memory, and to his deep interest in and services to photography. He was glad to add that the malady from which he had suffered, and which seemed at first to threaten serious suffering, did not finally either cause his death or produce the pain which had been feared. Mr. Reade died without pain, as quietly as if he had fallen asleep.

The following gentlemen were then elected members of the Society:—Messrs. R. Gillo, B. J. Edwards, E. Havell, A. Harrison, and Barnes.

Mr. G. Bishop and Mr. W. W. Hewitt were appointed auditors, and Mr. F. M. Goode was nominated for election on the council at the annual meeting. A paper on the collodio-bromide process, by Mr. H. Cooper, Junr., who, through ill-health, was unable to be present, was then read by the secretary.

Mr. HART suggested, in reference to getting rid of water of crystallization from the bromide of cadmium, that drying under a bell-jar with sulphuric acid or dry chloride of calcium was a better plan than the use of heat, as all substances giving off a sensible smell, such as iodides or bromides, were apt to suffer change when heat was applied. In reference to the use of the term organic matter in the paper, he would suggest, as a subject of investigation, whether the organic matter referred to as in collodion was an impurity, or a legitimate part of the substance in proper combination.

Mr. SPILLER said it appeared to be a difficult matter to drive off water from bromide of cadmium by heat without subliming the salt.

LIEUT. ABNEY referred to the keeping properties of collodion albumen plates as their most valuable quality. He had kept them for two years, and saw no reason why they should not keep four or five years, although, when long kept, he certainly preferred to give a somewhat longer exposure.

The CHAIRMAN, in proposing a vote of thanks, paid a high tribute to the value and practical character of the paper, and expressed his deep regret that imperfect health prevented Mr. Cooper from being present.

A paper by Mr. Woodbury, on photo-water-marking, was announced for the next meeting, and at the following meeting Mr. Rejlander proposed to open the question as to the cause of the cracking of negative films.

Talk in the Studio.

THE ECLIPSE EXPEDITIONS.—We understand from Mr. Brothers, who was stationed at Syracuse, that six photographs of the eclipse were obtained during totality. One of these, number 4, shows the corona "as it was never seen on glass before." The eclipse was well seen at this station. The clouds which concealed the earlier stages of the eclipse passed away from the sun about five minutes before totality, "disclosing," writes Mr. Brothers, "a scene I shall never forget."

THE ECLIPSE.—We have received from several correspondents card photographs of the eclipse, which are all more or less interesting pictorially, and all suggest capital moonlight effects, the appearance of a crescent moon being presented, generally in the midst of good clouds. The effect of light and shade obtained by sun, cloud, and a little foreground in a card by Mr. A. J. Bidens, of Northampton, is very good; Mr. R. Symons, of Tonby, sends one with fine cloud effects; Mr. H. C. Lee, of Blaenavon, sends us what he styles "a moonlight scene," but which is evidently a photograph of the eclipse, precisely similar to that of Mr. Symons.

THE SILL QUESTION.—A correspondent says:—"A few weeks back, an elderly lady, near Menhenniot, Cornwall, had a visit

from the excise-man, quite *promiscuous-like*. He had her up for having a still on the premises *without a licence*, and brewing *farmer's gin*. Fined £35 or three months. A somewhat similar case at Moretonhampstead, Devon: fine, £50. Photographers had therefore better be cautious and quiet on the still business. The most simple and reliable way to work the dissolving-dodge with one lantern is by fastening a piece of gauze to a spring soldered on to the tube; this can be moved up and down in various ways, and will prove a cheap and reliable make-shift. Attempting to use pieces of glass is a very *transparent error*."

OPERATORS' SPECIMENS.—A correspondent again calls our attention to the detention of the specimens and certificates sent by operators, seeking engagement, to employers. He says:—"On the third of December I replied to an advertisement in your columns from a gentleman requiring an operator, applicants to forward specimens and testimonials. I sent specimens and my original testimonial from my last employer. I have written to see if I could get them returned, but have received no reply. Having only a few specimens, it has been a serious drawback to me in applying for other situations." Such detention often is the result of neglect, but it is a cruel neglect, which should not occur. An operator, however, who sends away the original testimonial he possesses, acts foolishly, as a copy would serve just as well; and, as we have before advised, operators should take care to produce for themselves a few negatives, from which they could always print specimens.

IRON AND PYRO MIXED.—A correspondent of our Philadelphia contemporary says:—"I can recommend the following: I take a new iron developer, twenty grains to the ounce, and when I go out to make landscapes, I carry my pyrogallic acid in a bottle, and mix the dry acid on the spot, making about what I think I shall want in one or two hours. I put the dry acid into the iron developer, and shake until it is dissolved. I am guided by the work I am doing as to quantity, and the colour of the developer is a good guide as to the quantity of pyro you have put in. The more pyro, the darker the developer. It is well to keep it as much as possible in the shade, for it sometimes turns black and inky if exposed to the light. It is excellent where short exposures are necessary. I have done some good work with it, and although I prefer the iron alone for some work, I always have it at hand in case of need."

IRREGULAR FILMS.—The same correspondent says:—"I have been troubled with my collodion drying in holes on the plate, and have tried alcohol to reduce it, but almost always with bad results, and it has become a serious matter with me. A collodion reduced with alcohol loses its sensitiveness, and if it is not nearly absolute, it will dry in holes almost as bad as before reducing, on account of the water it contains. It became of so much importance to me, that I began at the root of the matter, and thought it up to the branches. In the first place, a good and well-balanced collodion is all right to use, but in keeping it must lose its ether much faster than its alcohol; then what does it want? Ether, of course; and experience has proved it to me, to my delight, for with collodion that was useless to me before without alcohol, I now have, by adding ether, a beautiful film, with which I can get the most delicate skies, and without any perceptible loss of sensitiveness."

New Inventions.

Provisional protection for six months has been granted for the following:—

No. 2649.—W. T. Henley and D. Spill, junior, both of North Woolwich, Essex. "Improvements in apparatus for the manufacture of compounds of collodion."—Dated 6th October, 1870.

"2948.—W. V. Wallace, of Clapham, Surrey. "Improvements in the preparation of surfaces adapted for painting photographic and other printing."—Dated 9th November, 1870.

"3036.—J. B. Sawyer, of Norwich, Norfolk. "Improvements in the preparation of printing surfaces in photo-mechanical printing."—Dated 19th November, 1870.

Letters patent have been issued for the following:—

33, Rue des Minimes, Brussels.

To Correspondents.

ADVICE TO CORRESPONDENTS.—We are at all times glad to advise our readers on any subject connected with the art upon which information can be given in this column; but to enable us to do so with efficiency, and without unnecessary waste of time and space, it is desirable that a few conditions should be observed by correspondents. All questions should be stated clearly, and written legibly on sheets of note paper, small scraps of paper and sheets of foolscap being equally unsuitable and inconvenient. Where several questions are asked, they should be kept distinct and numbered. Where processes and formulæ have been stated in our pages, it is better for correspondents to refer thereto than to request us to do so, as we cannot, with fairness, occupy space by repeating formulæ which have once appeared, merely to save a little trouble to individuals. Correspondents should use distinctive names or initials: such signatures as "A Subscriber," "An Amateur," and others of a general character being often adopted by a few correspondents in the same week leads to confusion.

SOUTH DEVON.—Rolling very much improves the appearance of all photographs; for small photographs it is almost imperative. They certainly never do anything like justice to the negatives until they have been rolled. As rolling presses can be had at a moderate cost, we certainly strongly recommend them.

A. D. O.—You will find various recipes for intensifiers in the YEAR-BOOK you have just received. You may use a pyrogallie acid solution consisting of—

Water	1 ounce
Pyrogallie acid	3 grains
Citric acid	3 "

To this add a few drops of a 20-grain solution of nitrate of silver at the time of using it. If you require still greater intensity, this may be followed by mercury and ammonia as you propose; but, except for reproductions, this is rarely necessary. We have pleasure in giving information and advice in this column to our readers. We make no charge for such advice.

RUSTICUS.—The largest manufacturers of silicate of soda or liquid glass are Gossage and Son, Widnes, near Liverpool.

S. M.—We regret that we do not know any firm who would undertake and understand the building of photographic glass-house, printing-room, &c. In all cases which we have known, the builder has required specific instructions for the individual structure he was about to undertake.

A SUBSCRIBER.—You will find in our YEAR-BOOK just issued simple instructions for the preparation and management of a nitrate bath, and also various particulars on rectifying baths in back numbers of the YEAR-BOOKS as well as in the NEWS.

C. C. COX.—The silver may be precipitated from your hyposulphite fixing bath in a metallic form without the use of sulphides by immersing strips of copper or zinc. The only disadvantage is, that the precipitated metal is apt to be slightly contaminated by the precipitant, copper or zinc. See Mr. Spiller's article in our YEAR-BOOK just issued.

AN AMATEUR.—The question of intensification would entirely depend on circumstances. If prints on ordinary paper were required, and the negatives were thin, then intensification would be employed. For many purposes negatives thin and without intensity are required; but wherever a negative with perfect detail has been obtained, there is no difficulty in adding intensity. Instantaneous photography depends on three things: chemicals in good condition, good light, and rapid lens. The two latter are very imperative, and, with these chemicals in ordinary good condition, will serve. A strong developer is always an aid. We have published many articles on instantaneous photography, but shall probably give the matter further attention.

F. D. W.—There is no work on enlarging with magnesium light. We have published various articles giving detailed instructions and formulæ. You will find particulars on p. 37 of our Twelfth Volume, and p. 75 of our Thirteenth Volume.

J. H.—The slight loss of gloss which follows the mounting of enamelled prints is due to the damping, which removes the extremely brilliant surface the collodion had acquired from contact with the surface of the plate glass. The remedy is, to use a substance for mounting which shall damp the print as little as possible. Hot glue will answer best; and, if skilfully used, will not, in any sensible degree, decrease the brilliancy of the surface.

GEORGE FIELD.—There are artists who undertake the retouching of negatives, some of whom have, we think, advertised in our pages. Amongst others you may apply to Mr. Croughton, 14, Church Road, Albert Road, Hammersmith. 2. We do not think photography is going down. Thoroughly good plain portraiture will always be in demand, in card and cabinet sizes. Salomon pictures will be in demand in some circles, and so with coloured work; but much depends on the district and class of customers. Enamels are not yet much in demand, but will become so, we have no doubt. In fact, much depends upon what the photographer chooses to bring into demand by doing it well and pushing it. 3. We are not sure.

A NEW SUBSCRIBER.—Of the lenses you mention we should prefer the triple.

J. C.—You may obtain pure coffee of a respectable grocer in the ground state, and may, we think, rely on it.

A SUBSCRIBER.—We do not recommend you to alter your studio to obtain a sloping front light. Rather make arrangements to exclude direct sunlight by means of thin semi-transparent blinds of tracing linen. It is probable that the arrangement of M. Adam-Salomon, which we recently described, may answer your purpose.

J. G.—The globe lens is not so rapid as the triple. We do not know what you mean by the "new globe lens." The question of the objects in question being in focus depends chiefly on the length of focus of the lens, the size of aperture, and the distance of the camera from the scene.

PASTEL.—In our own hands the formula on p. 101 of the YEAR-BOOK for 1870 answers exceedingly well. In the YEAR-BOOK just issued you will find additional information. The occasional samples of that prepared by Mawson and Swan have generally been good. The process produces capital prints on paper, opal glass, and transparencies, and also is an excellent agent in reproducing negatives; but it is not sufficiently sensitive for dry-plate purposes.

J. A. KAY.—Two parts of copal and one of shellac melted together. When fluid, two parts of boiled linseed are added, and afterwards ten parts of turpentine.

E. COX.—The name of the firm to which you allude is Breese and Co., Kelvin Grove, Sydenham. The letter was duly addressed and posted.

S. W. BORN.—Photographic transparencies of scenes in connection with the war may be obtained of Mr. F. York, of 87, Lancaster Road, Notting Hill.

E. F. F.—The cards are pretty, but there is a slight tendency to hardness.

CAPT. TURTON.—Chalk is not well suited for retouching negatives. For broad cloud effects, and similar things, lithographic chalk is sometimes useful. We prefer a lead pencil. You will find hints in Mr. Croughton's article in our last YEAR-BOOK (1870). There is also a good chapter in Newman's Harmonious Colouring, new edition. 2. We think the carbon process as practised by the Autotype Company unquestionably best. 3. We have not met with a case of such deposit as you describe, but could judge better on seeing it. Opal prints may be worked with water colours the same as paper prints, and, if well done, much resemble ivory. They should first be varnished, a matt varnish answering best.

J. CUNNINGTON.—Received.

Several Correspondents in our next.

CAUSES OF FADING IN SILVER PRINTS.

WHATEVER improvement may be made in carbon printing, or in modes of photo-mechanical printing, there is little doubt that silver printing will be commonly practised for many years to come, and possibly never entirely abrogated. At present it is the recognized method of producing prints, wherever a limited number only is required; and a system of working so wide spread, deep-rooted, familiar, and, in many respects, so beautiful, will not be easily superseded. In establishments of the highest class, and amongst the most conscientious photographers, it will probably be abandoned for the more trustworthy carbon process; but, as Mr. Bovey remarks, in his article on another page, the end is not yet. Hence it becomes important to re-examine at intervals the well-worn theme—the causes of fading in silver prints.

Accompanying Mr. Bovey's article we received a batch of prints, examples of the experiments he describes. The prints are brilliant, well-toned, on capital paper, and, where not tainted by decay, are sufficiently excellent to have warranted the greatest confidence in their stability. The cause of the decay is but too evident: the photographer's *betennoir*, sulphur, is the offender. The mode of its operation is only too common; but here it was intentionally induced, as a verification of opinions based on general observation. The impression is commonly entertained that mounting and mounting materials contribute seriously to the production of fading, and experience justifies the conclusion. But these are unmounted prints, in which the sole cause of decay is the contact with hyposulphite of soda, under circumstances calculated to produce decomposition rather than fixation. All the prints described by Mr. Bovey were well washed; but no amount of washing will remove sulphide of silver once present, nor prevent its spread throughout the print when once present in any part of it. The only contact which can take place between silver and hyposulphite of soda without danger to the print is that prescribed in a properly constituted fixing bath, where the latter salt is present in sufficient excess to form the sweet soluble double hyposulphite of soda and silver, which can be removed by washing, and leave the print without any internal cause of decay. Any contact of the silver print with hyposulphite of soda in smaller proportion than that in the fixing bath issues in a series of decompositions which end in the formation of sulphide of silver. The smaller the trace of hyposulphite the more dangerous to the print, because its action is not in such case always apparent at once.

Hence, besides the ordinary causes of imperfect fixation—namely, the continued use of the same solution, weakness, or acidity of the solution, prints sticking together, and extremely cold weather—other less suspected causes, such as the use of dishes or fingers which have touched hyposulphite, the dust of hyposulphite arising from dried up spilled solutions, and minute traces from other causes, are

amongst the fatal causes of the evil. In a private letter accompanying the prints, Mr. Bovey mentions some of the points suggested by his experiments. They are these:—

"First. The results of my experiments afford ample proof that sulphide of silver is the immediate cause of print fading.

"Second. Acting by catalysis, a minute quantity of sulphide of silver attacks each atom of silver of which the print is composed, until the whole is converted into a sulphurous compound. Atmospheric influences, especially humidity, hasten such decomposition.

"Third. Sulphur might be introduced by means independent of those alluded to in my paper. Stale albumen is probably a prolific source of sulphurous introduction.

"Fourth. There is every reason to show that decomposition is set up before the free nitrate is removed from the print, and, once begun, no subsequent treatment can prevent the destruction of the print. Discolouration occasioned by imperfect washing is not followed by the obliteration of the picture."

Fading is not a necessary condition of a silver print, and photographers should take care that it is not a probable condition. Produced with due care, and kept with ordinary precaution, the silver print has a reasonably long tenure of existence. The evil is not that a silver print must fade, but that it may. We fear the time will not arrive when it may be said of a silver print that it shall not fade; but there is no reason why the photographer should not be able to send out silver prints of which he can say that all preventible causes of fading have been eliminated, and that the chances of decay have been reduced to a minimum.

LOTTERIES AND ART-UNIONS IN CONNECTION WITH PHOTOGRAPHY.

A RECENT prosecution at Lambeth Police Court may be instructive to photographers, some of whom occasionally establish "art-unions"—or, in reality, lotteries—to give a stimulus to business. The case in question, as stated in the daily press, is briefly as follows:—

William Cannon, jeweller, 14, Kennington Road, and James Stevenson, landlord of the Oxford Arms, Westminster Bridge Road, were charged, the first as the principal in getting up a lottery, and the other for aiding and abetting in it. Mr. Poland, instructed by the solicitor to the Treasury, prosecuted; and Mr. Straight, instructed by Mr. Woodham, defended. The counsel for the prosecution said the proceedings had been taken under the 10th and 11th William III., and the 42nd George III., under which all lotteries were illegal, except when authorized by Parliament, and the parties getting up the same were to be considered as rogues and vagabonds, and be dealt with accordingly. He referred to two decisions in the superior courts, in which it was held that gifts presented to an audience were illegal, and contrary to the Lottery Act. In this case, the defendant Cannon was a jeweller, No. 14, Kennington Road, and the defendant Stevenson

a licensed victualler, keeping the Oxford Arms, Westminster Bridge Road. The attention of the authorities had been called to the lottery, and it was ascertained that books and tickets had been sold, and agents allowed ten per cent. The learned counsel read a bill-head, "The South London Art Union, under the management of Mr. William Cannon, 14, Kennington Road. Tickets 6l. each." The bill further stated that "the Union was established for the purpose of creating and extending a taste for the fine arts. The prizes will consist of photographs, plain and coloured in oil and water-colour; also engravings. Some good watches and jewellery will be issued. Great care has been taken in selecting the works of art, that they may be of the highest order." His Worship would see also, by the bill, that it was stated to be "according to Act of Parliament 21st and 22nd Vic. cap. 102," but by the evidence he should call it would be clearly seen there was no pretence for such a lottery to be brought within the provisions of that statute. After hearing several witnesses for the prosecution, Mr. Straight proposed an adjournment. Mr. Ellison said it was a proper request, and the case, which had created much interest, was then adjourned.

No decision has as yet been given; but it appears that no doubt exists of the illegality of the transaction, and as it appears closely analogous to some similar projects which have been carried out by photographers under the impression that "art-unions" had been legalized, it is important that the subject should be better understood. Hitherto, no photographic project of the kind has, we believe, been brought under the attention of the administrators of the law, but this appears to have been a piece of good fortune which might not be repeated. For reasons sufficient to the legislature, all lotteries were suppressed in this country by Acts of Parliament passed in the reign of William III and George III. About a quarter of a century ago, with a view to popularize art in this country, the idea of an art-union was projected; a scheme the subscribers to which received a certain specific equivalent in the shape of a work of art for the money contributed, and the chance of a valuable prize, also a work of art. This scheme was, of course, in the nature of a lottery, and contravened the law; but, as its aim was unquestionably good, certain acts of indemnification were passed, and eventually, in the year 1846, an Act entitled "An Act for Legalizing Art-unions" was passed. But this legalization only becomes operative under certain conditions. Art-unions were to be deemed lawful associations, provided they became incorporated by Royal Charter, or provided that the deed of partnership or instruments of association have received the approval of Her Majesty's Privy Council. It appears, then, that the matter is very simple. All schemes for the distribution of prizes by lot or chance, whether under the name of art-unions or not, are illegal still, unless the preliminary permission prescribed by the Art-unions Act is obtained; and all individuals and associations holding such lotteries or distributions are liable to the pains and penalties awarded to rogues and vagabonds.

CARBON PRINTING VERSUS SILVER PRINTING.

As our readers know, we have pleasure in permitting in these pages the utmost freedom of courteous discussion of all questions concerning photography and photographers, and the candid expression of reasonably intelligent views in connection with the art, whether they accord with our own convictions or not. Where we conceive the opinions expressed are based on inaccurate or insufficient premises, or where it seems that the conclusions do not follow logically upon the facts, it becomes our duty at times, in publishing the views of correspondents or contributors, to point out the source of the error. On another page we print the impressions of a photographer, of large experience, as to some of the causes of fading in silver prints, and the relative value of silver and carbon printing, upon which we think a few remarks desirable. On the subject of silver printing, where Mr. Bovey's experience is large, we agree generally with his conclusions. Upon the subject of carbon printing, his remarks, based rather upon observation than experience, or upon the experience of others

rather than his own, we think his conclusions erroneous; and the error is twofold, being based upon insufficient evidence, and upon a fallacious estimate of the tendency of the evidence adduced.

Mr. Bovey states that, notwithstanding the assiduous effort with which carbon printing has been pushed for half a dozen years, it has met with a slender amount of success. Photographers generally, with unrelenting obstinacy, produce their prints in the old-fashioned way, in spite of the speedy decay of much of their work; and he thinks that this persistency is not due to the influence of vested interests, or to the tenacity with which men stick to something with which they are familiar, and which answers their purpose moderately well, rather than abandon it for something unfamiliar, but is due solely to the deficiency of the unfamiliar substitute proposed. Carbon printing, it is affirmed, produces inferior results to silver printing, and at a greater cost. The fact of the alleged non-success of carbon printing is also incidentally adduced as an argument against its value, as "there are few so blind as to lose sight of the fact that a ready adoption of improvements is the surest road to success." Now as we, with at least as ample means of being familiar with all the evidence as the majority of persons interested in the question, believe these conclusions to be altogether fallacious, it is our duty briefly to express our convictions, and the grounds upon which they are based.

It is implied that carbon printing has been tried, and proved a failure. But the simple fact is, that it has not been tried. We doubt if there are a dozen, or even half a dozen, portraitists in the kingdom that have tried it on any commercial scale. We do not know one in London who has done so. We do not know one anywhere who has done so, and given it up. We know of some who are making special arrangements for its general adoption. In every establishment where it has been introduced in earnest it has continued in use, and in all with which we are personally familiar it has given satisfaction.

On the score of beauty, Mr. Bovey unconsciously admits the superiority of carbon - or, rather, permits one of his witnesses to do so: "With a good negative the Autotype can show superior results, but with the usual run of negatives the process is a mistake." This witness proves considerably too much; he proves that his usual run of experience is with bad negatives, and is, therefore, rather condemnatory of the negatives than the printing process; and next, that with good negatives carbon is superior to silver. As all negatives *should* be good ones, and as the majority *might* be, a process which presses upon the photographer the necessity of producing them should be encouraged rather than condemned. Nothing more encourages carelessness in working than immunity from its consequences. When, some years ago, the practice prevailed of masking negatives to print in what was termed a French background, slovenly operating was not unusual, and stained, imperfect backgrounds common. When the card mania set in, clean working became a necessity, and soon became the rule. Further, if with good negatives superior results to silver may be obtained with carbon, but with faulty negatives less perfect results, the conclusion follows that printers are more familiar with the capacities of silver printing, and can better adapt them to "dodge" the defects of the negative; and that an equal familiarity with the possibilities of carbon printing will probably produce equal skill in humouring faulty negatives.

That carbon prints from the same negatives are, in all instances, equal in beauty to silver prints we are not prepared to affirm. In many cases the comparison is in favour of silver printing in richness, depth, and transparency. This is not surprising. The perfection of silver printing is the result of thirty years' experience with many thousands of workers; carbon printing is the result of six years' experience of a few individuals, pro-

bably not as many in units as the silver printers have been in thousands. The fact that carbon prints have been produced quite equal in beauty to silver prints—and we have seen many as perfect as could be desired—proves the possibility; the rest is a matter of experience and practice.

The question of cost requires but few words. Until carbon printing has become much more general, no fair comparison can be made; but it is important to bear in mind that M. Braun, who has worked carbon more extensively than any other photographer, finds the cost less than that of silver printing, and his evidence is the most weighty which can, for the present, be adduced.

The suggestion that carbon printing must be wrong in some particular, because it has not become more common, scarcely requires serious refutation; no estimate of the worth of anything is so fallacious as that based upon its progress in a limited time, especially if the said thing have to supersede something which has become universal, familiar, easy, and affords a temporary success. Apparent gain, obtained immediately by easy and familiar means, is generally preferred by the majority of mankind to advantage possibly higher and more certain, but certainly more remote, because change, effort, and training must intervene before it is acquired. The history of every advance in civilization demonstrates this. No reform—social, moral, or political; no improvement in science, art, or industry—has ever been secured without a struggle, often a protracted one, not simply with vested interests, but with established habits and ideas, generally defended with an obstinacy generally in direct proportion to their absurdity, the arguments advanced in their defence being rarely more cogent than that common at one time amongst old-fashioned farmers in defence of the now abandoned lumbering wooden plough, to the effect that “an iron ploughshare caused weeds to grow.” Carbon printing has been in existence as a possibility for about six years. It has been the subject of constant experiment and improvement during the whole of that time. Some of the most specific improvements in point of facile practice have been made within the last year or two. The whole facts gravely weighed, it would have been a marvel if it had made much greater progress in superseding silver printing than it has done. Photographers are already familiar with silver printing; all their plant is made with a view to its practice; all their experience is based thereon. Professional photographers must produce immediate results to live, and they cling most naturally to the process which gives these results. If successful, they are too busy to experiment with radical change; if they are unsuccessful, they cannot, or think they cannot, afford it. Amateur photographers are generally chiefly interested in getting some results from their negatives, printing at all rarely present as many charms for them. And all are disposed to believe that the one cardinal defect of silver prints, instability, is not an inherent one; that it is due to accidental carelessness in production, which ought not to occur again; that it is due to some incidental neglect in preservation, which is the fault of the custodian; that it is due to some accidental defect in paper, cardboard, or mounting material, which is not the fault in the process; or that at least something will shortly turn up to give the prints the absolute permanency so much desiderated. With the actual beauty of result which thirty years' experience has rendered easily attainable in silver printing, and the universality of its practice, it is not surprising that the unfamiliar six-year-old bantling, carbon printing, should have done little as yet to supersede the old, familiar, and effective, but unstable silver process.

The notion that carbon printing has been assiduously pushed appears to us to be curiously erroneous. Pushed by whom? Mr. Swan, to whom its existence as a possible process is due, never pushed it. He is by nature and habit a student; by occupation an exceedingly busy man,

having the personal management of a large and important business. By an over-exhausting effort, he worked out carbon printing to a very perfect practical issue, on a commercial scale. But he was neither by nature nor opportunity a propagandist. It passed into the hands of a company, who find their account in working it very extensively and successfully, rather than in spending much effort to induce others to do so. Who, then, has had a specific interest in pushing the matter? The complaint has often reached us that the facilities for getting the materials are insufficient. The fact that what used to be called a restrictive policy, in imposing license charges, at one time prevailed, has been the subject of much comment. The company seem to have been impressed with the conviction that if they continued the successful and profitable practice of the process, the time must come when it would be in demand, and have rather occupied themselves in preparing for the perfect and profitable manufacture of the materials for present and probable demand, than in extensive or systematic propagandism. The chief pushing the process has received has been given by ourselves and other photographic journalists, who, in the discharge of a manifest duty, have persistently kept before photographers a knowledge of the fact that permanent printing was a possibility, and that the “bye-word and shame” of instability was no longer a necessity in the productions of their art.

We might multiply arguments on this subject; but we have already exceeded the space we can devote to it. The subject is important, however, and worthy of consideration. The written opinions by Mr. Bovey probably represent the thought or spoken ideas of others, and it becomes our duty, therefore, in giving them a concrete form, to point out wherein they are erroneous. Instability is the stigma of the art: a process exists whereby it can be removed. The natural opponents in the shape of vested interests, conservatism, sluggishness, and honest attachment to the old method, interpose strong barriers against radical change, and it becomes our duty to aid in removing unnecessary, fallacious objections to improvement. Mechanical printing processes, however perfect, will not, it is probable, ever take a place in ordinary portraiture where a few impressions are required. Carbon printing, we believe, will do this in the best establishments, and at no distant day.

THE FORTHCOMING INTERNATIONAL EXHIBITION.

The following extracts from the conditions for the guidance of exhibitors in the department of Fine Arts, in which photography is classified, will be useful to many of our readers. After enumerating the objects included in the class, which consists of all kinds of paintings, sculpture, carving, modelling, engraving, lithography, architectural designs, tapestry, embroidery, carpets, designs for decorative art, and copies of ancient works of art, as well as photography, the rules proceed:—

* II. No artist can be allowed to exhibit more than two works of each kind, one of which at least must not, except under special conditions, have been previously exhibited in London, but he may send works of as many different kinds as he pleases: thus the same artist may send for admission two oil paintings, two water-colour paintings, two paintings on enamel, porcelain, &c., also two sculptures in marble, two in wood, &c.

III. Paintings and sculptures may be either separate works, or form part of the decoration of objects of utility, e.g., vases in pottery, fans, panels for furniture, wood carving for furniture, &c.: provided that such objects are entitled to be classed as works of Fine Art.

IV. All works of Art, except reproductions of ancient and

* In accordance with the recommendations of the Fine Arts Committees, this rule will be suspended in the first Exhibition; artists will consequently be at liberty to submit any number of works, whether previously exhibited or not.

mediæval works, must have been executed by living artists, or by artists deceased within five years.

V. A producer will be permitted to exhibit reproductions of any number of ancient or mediæval works of art.

VI. Foreign works may be sent with the Certificate of admission given by the respective Governments of the countries in which they are produced. Foreign works sent without such Certificate, and all works of British subjects, will be submitted to the approval or rejection of judges appointed for the respective classes, whose decisions will be final, and may be ascertained on application at the Exhibition Building.

VIII. The Commissioners cannot undertake to receive any package which may be presented by carriers. Foreign artists whose works are not sent through a Foreign Government should consign their works to an agent in London.

IX. Each picture, drawing, or series of drawings relating to one subject, must be in a separate frame, except very small miniatures, or sculptured gems, any number of which may be placed in a frame not exceeding a foot square.

X. All pictures and drawings must, excepting in special cases, be in gilt frames. Drawings with wide margins are inadmissible. Excessive breadth in frames, as well as largely projecting mouldings, may prevent pictures obtaining the situation they otherwise merit; and oval frames should be avoided, as they are difficult of arrangement.

XI. The prices of works to be disposed of, carefully described as in the next paragraph, may be communicated to the Secretary.

XII. A list of the works submitted for approval must be sent with them. The title of the work and the artist's name should be written upon or securely attached to each object, as well as the number (if there be more than one) to which it refers in his list; particular accuracy is requested in this respect.

XIII. All objects of Fine Art must be delivered at the Exhibition Building, South Kensington, into the charge of the proper officers, unpacked and ready for immediate exhibition, and free of all charges for carriage, etc., on the following dates:—
On Wednesday, 15 February, Sculpture not applied to works of utility.

On Thursday,	16
On Friday,	17	..	Painting applied to works of utility.
On Saturday,	18	..	Sculpture applied to works of utility.
On Monday,	20
On Tuesday,	21	..	Eugraving, Lithography, Photography, etc.
On Wednesday,	22	..	Architectural Designs, Drawings, and Models.
On Thursday,	23	..	Tapestries, Carpets, Embroideries, etc.
On Friday,	24	..	Designs for all kinds of Decorative Manufactures.
On Saturday,	25	..	Copies of Pictures, Mosaics, Enamels, etc.
On Monday,	27	..	Painting not applied to works of utility.
On Tuesday,	28

XIV. To every work, when exhibited, will be attached a label, prepared by Her Majesty's Commissioners, which will contain the following particulars:—

1. The subject.
2. The artist's name.
3. His address.
4. The price, if for sale, unless the Exhibitor objects.
5. The date of execution.
6. Any explanations.

XV. Forms of application for admission will be forwarded on demand.

AMERICAN CORRESPONDENCE.

EMIGRATION OF PHOTOGRAPHERS TO AMERICA.—THE SCARCITY OF COMPETENT PHOTOGRAPHERS.—CHLORIDE OF PALLADIUM FOR TONING GLASS POSITIVES.

Emigration of Photographers to America.—In your issue of December 16th, you published Mr. Schone's letter on this subject, and I only allude to it to bring up one or two other remarks on the same subject. From time to time I

meet a great many photographers from Germany and England, and I always take pleasure in assisting them to situations when in my power. Intercourse with them has convinced me that they are not accustomed to driving as we are here, from morning until night, and I have seen them sometimes look appalled at the work that is done in one of our American studios in a single day. When the sun shines the people go to the photographers in swarms, and they, of course, endeavour to make as many negatives as possible, lest they lose some of their custom. This, of course, compels all hands to be active, and the hours that Mr. Schone has given as the working hours here, are hours of real constant toil, one sitting following another as fast as possible, and not much time allowed over each subject either. A photographer from abroad, if he be accustomed to take things more leisurely, will have to become accustomed to American hurry and drive before he can gain the best of wages. Still there is much to encourage foreign photographers to come here, and I am sure we are glad to have all the talent you can spare us.

Some of our most eminent artist photographers—Carbutt, Kurtz, Fennemore, Scholtin, Roche, Cremer, Openecke, Merz, and many others—are foreigners, and just as much esteemed as our own native talent. We have a large country here. With a little capital one can readily begin, and soon rise if he be content to live frugally in the beginning, and have a stout heart. There is much jostling and grinding down of the weak, but if a man is persistent and pushes, he will succeed gloriously.

The Scarcity of Competent Photographers is becoming quite a serious matter with us, and there is a fine chance for the young talent that may enter the field. Is it the same with you? There are plenty of incompetents, but for real good photographic operators and printers there is an active demand now.

Photography has grown and advanced, but the number of good tasteful operators has not increased in due proportion. There are general reasons for this. One is, that the young men do not see sufficient promise of remuneration in the business to attract them to it, perhaps. Some argue that photography promises as much as any mechanical vocation; but, then, will you class photography with mechanics? If you will, drop that idea at once. Photography is an art, and the time is very rapidly approaching when it will be such an art that only the educated and skilled can reach up to its requirements, and if we are not careful it will get ahead of us. "What are we to do, then?" you ask. I suggest the following:—

Take apprentices and educate them in all the mysteries of our black art. The day when any mechanic can take a few lessons in manipulations, buy an outfit, and then establish himself as a professional photographer, is over, and the sooner that fact is realized the better for blessed photography.

If your son desires to become a painter, he must go through a course of study and practice to fit him for his chosen vocation; and so with all other trades and professions. So it should, and so it must be hereafter, with photography, if we desire to maintain it as an art. Select young lads, fresh from school, whom you think have the taste and talent, and bear them up until they are taught thoroughly every branch of the art, from cleaning glass to posing and lighting the model. This will take, to do it right, from three to five years. When your fledgling is competent, then fly from under him, and either let him go it alone, or employ him on wages on which he can live and lay by something, or take him in as a partner. Our conviction is, that if this were done, photography would in a few years be entirely cleared of incompetents, and would be more respected, more sought after, more patronized, and be able to boast of having enough men of talent in it to cope with its continued and ever to be continued rapid growth.

Harrison's Head Rest.—Excuse me if I bring up a personal matter. I see Mr. James Harrison, in your own pages and in those of a contemporary, expresses himself rather sore, because Dr. Vogel has described in your pages a novelty pertaining to a head-rest which happens to bear my name. Because Mr. Harrison chooses to enact the Rip Van Winkle, I should not be accused of doing him a wrong, for I beg to assure him, with the best of feeling, that I have had no intention of doing him an injury, and I will prove it to him. About the middle of 1867 I observed, in an English journal, a description of his head and body rest, and was at once struck with its utility and advantages. Supposing that no one would be so foolish as to import such an apparatus when it could be made at home so much cheaper, I re-published the article alluded to in the *Philadelphia Photographer* for January 1867, page 250, hoping that some of our manufacturers would take the hint, and manufacture the machine for the American public. No one did it, and, thinking over the matter, I devised what I considered an improvement, and what would enable the photographer to do with two or three less screws to work than I understood Mr. Harrison's to have. In the March (1868) issue of *Philadelphia Photographer*, page 74, I described my improvement, and, without saying it was mine, did give Mr. Harrison full credit for his part of the invention. In 1869 I made still further alterations. The machine seemed too heavy for some of our people to lift, so I put it on wheels, so it could be moved about, with a contrivance to throw it off the wheels when it was in actual use. This I described in the February issue of the *Philadelphia Photographer* of 1869, and again alluded to Mr. Harrison. Dr. Vogel, in his description in your pages, forgot that last alteration. Now if Mr. Harrison will take the trouble to see the pages of the magazine to which I have alluded, I am sure he must feel that I have endeavoured to do him full justice. I have seen his machine in New York, but, as I said in the beginning, he cannot hope to reap benefit from its sale here, for duties, freight, &c., would make it too costly. If he has never seen mine, I will gladly present him with one if he will bear the expenses from here to his studio; then let him call in his neighbours, and before them let him decide whose is the prettiest and the best. I should not have said so much, for I despise anything like controversy, but I did not want Mr. Harrison to feel that I had deliberately injured him, or that Dr. Vogel would either.

Chloride of Palladium for Toning Glass Positives.—One little practical dodge, and I am done. I will give it to you as taken down from my friend J. C. Browne Esq., to whom I am indebted for the idea:—"Now that slides for the magic lantern are so much sought after, the best method of printing and toning such pictures is a matter of considerable interest. In the treatment of glass positives that require additional contrast after fixing, many chemicals have been suggested, and, after a careful trial of their merits, I am disposed to consider chloride of palladium as the most reliable chemical that has come under my notice. Its action is perfectly manageable, it is easy to prepare, it will not stain, and it gives uniformly good results. The toning solution is made as follows:—Add six drops from the stock bottle of chloride of palladium to each ounce of water. This solution should be of a delicate straw colour. No other manipulation is required. After the plate has been developed and fixed, wash as usual; then apply the toning solution in the same way as you flow the developer. Its action will be quick, giving a rich black tone to the positive. Wash well, dry, and varnishing is desirable. Allowance must be made in toning for the kind of light to be used in the lantern. The oxyhydrogen, magnesium, and electric light will require the positives to be more dense than when coal oil is used for illumination.—Truly yours,

Philadelphia, January 2, 1871. EDWARD L. WILSON.

WASHED AND FUMED PAPER—A NOTE.

BY COLONEL STUART WORTLEY.

I THINK the following fact worthy of consideration. During the late hard frost my printing was entirely stopped. It so happened that many prints remained half printed in the various frames when operations were first suspended. After the lapse of sixteen days printing was resumed, and the frames with the unfinished prints were put out and finished. They toned perfectly, and are now not to be distinguished from prints printed and finished within twenty-four hours. You know my opinion of the great value of the washed and fumed paper; but I was hardly prepared for the fact that the effect of the ammonia would have enabled a print partly commenced to finish perfectly after the lapse of sixteen days.

There was, of course, no means of supplying fresh ammonia, and the only ammonia used was that which started the prints at the commencement.

RETOUCHING NEGATIVES.

BY B. J. EDWARDS.

THE practice of retouching negatives has now become almost universal, notwithstanding many objections which have been urged against it. In skilful hands, there is no doubt of the advantages to be derived from the moderate use of the pencil on the negatives; if the retouching be carried to excess, the result is often both unpleasing and untrue to nature. The more perfect the negative, the less retouching will be needed; it is quite possible to produce a negative so perfect in all its gradations of light and shade that no human skill could improve it; but such work is rarely obtained, and depends quite as much upon the suitability of the model as upon successful lighting and manipulation.

A badly-lighted and under-exposed negative cannot be made perfect by retouching, but for the removal of slight defects, such as freckles, softening the texture of the flesh, and rendering delicate details in the shadows, the pencil, in the hands of an artist, is an invaluable aid.

In order to work successfully on the negative, it is necessary to alter the surface of the varnished film, giving just sufficient tooth for the lead-pencil to work upon. If the negative requires much retouching, a sharper or rougher surface is needed than for a slight retouching, which can often be effected upon the smooth surface of the film; if more be necessary, the following will be found a simple and effective way of preparing the surface to work upon. Having varnished the negative in the usual way (allowing the varnish to soak well into the film), let it cool, and pour rapidly over it a little methylated spirit, repeating the operation two or three times, according to the surface required. Do not allow the plate to soak in the spirit, the object being merely to remove the varnish from the surface of the film; when dry the film will be hard and not easily scratched, and will have a fine dead surface for working upon with the lead-pencil. I prefer a hard pencil; H or F I find the most suitable; if a very soft lead be used the effect will be coarse, and it will be difficult to revarnish without removing the pencil marks. For working upon the flesh tints very fine stippling gives the best effect, the highest lights being put in with a more solid touch. For lightening broad shadows it is a good plan to use a little of the powdered lead, applied with a leather stump or the tip of the finger. The small spot of bright light in the eye may be put in with the point of the pencil, taking care to keep it in the right place, according to the lighting of the face. This simple matter is often neglected, and the spot of brightest light placed on the *shadowed* side of the face. The pupil of the eye will be much improved by carefully removing the film with a sharp needle; this gives great brilliancy.

For the hair it is better to use a little of the powder lead; or it may be finished with a few broad touches of water colour, laid on the second coat of varnish.

After retouching, the plate may be revarnished without

injury by using the varnish cold and not too dilute; when just set, hold the plate before the fire until it becomes transparent in the shadows. I may just mention that I use the "Sohnee" varnish, but any good hard negative varnish will serve.

THE PRESENT POSITION OF AUTOTYPE PRINTING.

TO WHICH IS ADDED, A FEW HINTS CONCERNING THE CAUSES WHICH AFFECT THE PERMANENCY OF SILVER PRINTS.

BY W. T. BOVEY.

WITH an earnest perseverance, due to a great cause, the "best friends of photography," during the past five or six years, have been adjured to eschew the error of their ways, by yielding up those prejudices which blind their eyes to the advantages of carbon printing. In vain has it again and again been reiterated that silver printing is on its last legs. In vain has it been shown that a silver print, although a thing of beauty, is not a "joy for ever," but, like unto Jonah's gourd, is doomed to a speedy decay. Yet, despite the protestation of those disinterested admirers who, of course, have no vested interests to maintain, the best friends of photography turn a deaf ear to the voice of the charmer, and continue to produce their pictures in the old-fashioned way.

The cause of this unrelenting obstinacy is, of course, attributed to the opposition of those who openly or covertly offer objections against the Autotype process; and it is almost angrily insinuated that "vested interests" are the prime movers in the work of counteraction. This assumption is simply nonsensical, for although "vested interests" might bar the way of progress for a time, yet true progression will readily assert itself in a way that speedily scatters vested interests to the winds, for there are few so blind as to lose sight of the fact that a ready adoption of improvements is the surest road to success. I have no hesitation in expressing my opinion that the only reason why silver printing remains the chief favourite among photographers is, because the Autotype system cannot take its place on account of the deficiencies of the latter process. I freely concede that men are naturally conservative, and innovations do not, as a rule, meet with a favourable reception; yet it must be conceded that an improvement which has been assiduously pushed for half a dozen years, with only a slender amount of success, must be wrong in some particular.

In reference to the matter before us I have been at some pains to sift it to its very bottom, and I have accumulated a mass of evidence which makes my opinions no longer a thing of doubting. The Autotype system of printing does not realise its early promises. One gentleman, well known as an extensive worker of the system, candidly confessed to me, that the process was quite as expensive as silver printing, and infinitely less satisfactory in the beauty of its productions. "I make it a practice," said he, "to strike off a silver print from each negative before proceeding with the carbon proofs: as a rule, these last admit of no comparison with the first. The only thing that can be said in favour of the Autotypes is, that they are permanent." Another gentleman, better known still as a carbon printer on an extended scale, remarked, that "in his experience, he found the cost of carbon printing to be greater than printing in silver, and the results by no means so good. With a good negative," he continued, "the Autotype can show superior results, but with the usual run of negatives the process is a mistake."

In pushing these inquiries, I was influenced simply by an ordinary business precaution, for at the time I could as easily have made arrangements for carbon printing as for printing in silver. The ocular as well as oral proofs I received decided me on a present adherence to the latter course. I say a "present adherence," because I am per-

sueded that silver printing must, sooner or later, give place to the mechanical methods which are progressing towards perfection; but the end of silver printing is not yet. Such being my impression, I lose no opportunity of studying the conditions that have made silver prints a by-word and a shame.

The course I take in tracing out the cause of a defect is to search out a way of producing such defects at will. The remedy then becomes obvious. Acting on the principle described, I have just unkenneled as goodly a show of yellow streaks and jaundiced prints as ever disgraced a London photographer's show-case or a lady's gorgeously-bound album. It will be readily understood that experiments of the kind to which I invite attention require months of time to complete, and it is months since that the prints now before me were packed away as brilliant and blooming in appearance as the most exacting could wish. The causes of their decline remain to be related.

The introduction of an agent of decay was a matter simple and easy—I fear, much too easy.

Batch number one. Toned and fixed in the usual way, afterwards placed in a shallow tray of water, where they remained some time before a second water was introduced. Results: a slight yellowness, but as yet no change of marked importance.

Batch two. A minute trace of hypo added to the water in which the prints were washed prior to toning. I noted at the time that the indications of the sulphurous presence were almost imperceptible. Results: some prints are yellowed and partially obliterated, others gone in streaks, some only at ends or corners; but all are doomed.

Batch three. A little hypo solution dropped into the water in which the prints rested after toning and previous to fixing. Results: similar, but not in degree as bad as batch two.

The whole of the prints underwent a thorough final washing in a large bulk of water, and appeared, when dried, as perfect in colour as could be desired. Yet mark the results after the seasoning of a few months.

In reference to this matter, it might be urged that photographers are not usually in the habit of adding hypo to their washing waters. Not intentionally, I grant; but it must be remembered that the printing department is sometimes conducted by ignorance and carelessness. More the pity! Yet the cause is soon explained. The photo printer is too often regarded in the light of an unskilled labourer, and is paid and respected accordingly. A printer's position was never a very desirable one, but that demon competition has now pulled him down into a state of degraded slavery. I had occasion recently to advertise for an assistant printer. The applications were, alas! too numerous. The appearances of the applicants varied from a cross between a dog-fancier and pugilist to a swell out at elbows as well as out of luck. On questioning those poor fellows, I found a realization of the old story: they were hanging to a business which nature did not qualify them to adorn. Much intelligence would hardly exist on a printer's wage.

I have heard printers boast of their time-saving skill in toning with one hand and fixing the prints with the other, both operations being conducted at one and the same time—a feat which, to my mind, is suggestive of occasional grave mistakes. With my own eyes I have seen an assistant fixing prints, and splashing an occasional drop or two of hypo into a can of water intended for washing a batch of untoned prints. In short, there are many ways by which a trace of hypo might be introduced into the first washing water without its dread presence being suspected; and the prints washed therein, fair and unblemished, are sent out into the world to fade and perish, causing a verdict to be passed on silver prints generally: "*They are doomed to decay!*" And photographers themselves are wont to entertain the same delusion. I am of opinion that care, united with proper treatment (*care* is

sometimes the cause of the mischief), would prove sufficient to add considerably to the tenure of a silver print's existence. Quantity and quality are qualities difficult to unite. Cheapness makes the former a necessity. Again, more the pity! Yet, quality apart, the dishes in which the preliminary washings are conducted might be kept entirely free from hypo by giving to each a thorough washing prior to use; and the utmost care should be exercised to prevent the obnoxious agent from mixing with the first washing water; and the consequences that follow a deviation from this rule should be pointed out to each printer and assistants. They should also be taught the necessity of giving an abundance of water to the prints for the first dip they get subsequent to fixing, for it is *not* the time of washing they receive that adds to their stability, for an hour's washing in an abundance of water imparts greater advantage to the pictures than a week's soaking in a small pan or dish could accomplish.

Silver printing has doubtless attained a high state of perfection, so far as beauty of results is concerned. Make such results permanent, and the process cannot sink into oblivion until the day when the heliotype or Woodbury-type work shall be in a position to challenge comparison with the best silver printing.

ASTRONOMICAL PHOTOGRAPHY IN AMERICA.

BY DR. H. VOGEL.*

OUR readers will probably remember the details of the eclipse observations in America on the 7th August, 1869. The extensive nature of the means employed on that occasion, and the enthusiasm with which many hundred photographers and men of science devoted their time and labours to bring about a successful issue, were alone sufficient to testify to the efforts on the part of the American nation to do something in the cause of science, and to contradict the oft-repeated statement made in Europe, that America never cultivates science for itself alone, but always with a view to some material benefit. But to what material benefit would an investigation of the protuberances of the sun lead? Nobody, surely, would believe, for instance, that an examination of them would be instrumental even in affording us a larger supply of hydrogen! Again, it is not unfrequently asserted that, taking into consideration the wealth of resources existent in America, and means available for the prosecution of scientific investigation, there are, in proportion, but few researches or inquiries instituted in that country. This complaint may, in part, be a true one, but then, it should be remembered that America is a land in which, at present, there are but proportionately few scientific men. As regards the subject of photographic astronomy, however, there is no ground for any such reproach, for in respect to that branch of science the Americans are exceedingly well posted. The results obtained last year during the eclipse of the sun surpassed the most sanguine expectations, and the previously well known photographs of the moon and sun's spectrum obtained by Rutherford are altogether without rivals, and constitute, in every way, real triumphs in American science and American photography.

Rutherford is an amateur, who has dedicated his time and means to the worship of science. On the very first day of my arrival in America, I had an opportunity of making the acquaintance of this amiable, as likewise modest and intelligent, American; his instruments, his laboratory, and observatory, were all inspected by me, as, indeed, I have stated in my first letter from America. Some time later, I enjoyed a further opportunity of improving my acquaintance, and was then fortunate enough to become known to Mr. Chapman, the assistant to Mr. Rutherford, to whom I owe special thanks. The gigantic proportions of the sun's spectrum, measuring

2.1 metres in length, was obtained by Rutherford in fifteen different sections, and in a very simple manner. He fitted to the spectroscope a camera without lens, and, by pulling out the eye-piece of the apparatus to some distance, employed the same as the lens, to throw a picture upon the focussing screen, where, after being sharply focussed, the image was photographed. Owing to the limited field of the apparatus, the coloured spectrum can only be secured bit by bit, and but to that extent, obviously, to which the rays act upon the sensitive film. Rutherford's representation of the spectrum from 1885 of Kirchhoff's division (before F in green) to beyond 5,000 of the Angstrom's sketch of the spectrum lines (that is to say, beyond H' in violet). The Rutherford spectrum, therefore, contains more than the Angstrom spectrum table, and above $\frac{2}{3}$ of Kirchhoff's.

If the Rutherford and Kirchhoff's spectra are compared, there will be found several differences to which attention should be called. In the first place, the lines of Rutherford are much richer; where, for instance, Angstrom shows us but a glimmering outline, a shadow, or separate markings, Rutherford gives clearly defined lines close together, as in 3,525 and 3,572. A simple line in Angstrom's sketch 3,539, becomes a double line in Rutherford's, and between 3,557 and 3,547, where nothing at all is shown by Angstrom, we find in Rutherford's photograph one strong, and four weaker, but well marked lines.

Some few instances are only quoted here, but they might easily be multiplied. Moreover, many lines which appear characteristically marked by Rutherford are represented in Angstrom's and Kirchhoff's tables as quite subordinate, as witness 3,040, 2,936, and 2,720.

These discrepancies are explained by the difference between the sensitiveness of the retina and that of the photographic film; where with us there is light (as, for instance, in the yellow), there is to the plate profound obscurity, and *vice versa* as regards the ultra-violet portion of the spectrum. For this reason photography renders important assistance to the eye in the depiction of the spectrum.

In the same way as certain fresh fields of the spectrum (to wit, the ultra-violet) have been discovered by means of more sensitive chemicals, so, in like manner, have new lines been found in portions of the spectrum already investigated; and it will now be the work of the spectroscopic observer to determine the reason of these lines. And to conduct such an investigation it will be necessary to examine and photograph different artificial spectra with bright lines, and especially the numerous ones in the iron spectrum, in order to ascertain whether these new lines of Rutherford belong to them or not.

One point is of importance, viz., that in order to obtain a means of instituting closer comparisons between the Rutherford and Kirchhoff's spectra, they should be reduced to the same measurements. The Rutherford spectrum should be produced of the same dimensions as that of Kirchhoff, and this could surely be done by enlarging or reducing the same by means of photography. At any rate, the results of Mr. Rutherford would then be more appreciable by scientific men, who, as a rule, will have little to do with photography, from the fact that they do not at all understand its capabilities.

Rutherford's photograph of the moon has already been mentioned in this journal. I should mention that in Germany only one example of moon photography is known, whereas at Rutherford's studio I saw no less than three. Of these, that of 1865, which is known to us, is certainly the most beautiful and clearest, the others being less sharply defined. This latter defect is due to the agitated state of the atmosphere, to which I referred some time ago, when describing the large telescope of Schroder, in Hamburg; this phenomenon acts in a prejudicial manner, even with very short exposures (as, for instance, when only of one second duration), and for this reason a perfect picture is more the result of good luck than anything else.

* Photographische Mittheilungen.

The photographs of the stars obtained by Rutherford I have also mentioned in a previous letter, but refer to them again, in order to describe a few interesting details in connection therewith. As may be imagined, pictures of such microscopical size as these lesser luminaries may easily be mistaken for collodion spots, and in order that no doubt shall exist on this point, Rutherford has recourse to an exceedingly ingenious device. He places a sensitive plate in his apparatus, and secures a photograph of the stars while the clockwork of his telescope and camera follow these luminaries; then he checks the motion of the telescope for a period of thirty seconds, sets it again in motion, and exposes a second time. In this way a second picture of the stars is obtained close to the first one; or, in other words, a double picture is secured, similar to that produced when the camera during exposure has been moved, and with this it becomes an easy matter to distinguish the double pictures of the stars from specks in the collodion, which do not frequently appear doubled. After the second picture, Rutherford again checks the motion of the telescope for a short time, leaving the plate still exposed, and by this arrangement the brighter stars trace a fine line upon the plate, showing the exact direction in which they are moving.

All astronomical photographs are taken by Rutherford upon wet plates, coated, in the first instance, with albumen, as he finds the collodion film is, in this way, more securely fixed, and less liable to contraction, a circumstance of considerable importance when the minute pictures come to be measured.

(To be continued.)

PRELIMINARY COATING & POLISHING.

BY J. W. WILKINSON.

THERE is scarcely any operation in a photographer's routine of work so troublesome, laborious, and important as plate-cleaning. Detergents, polishing liquids, &c., may be used, but still the trouble and labour are very great, and the results are not always satisfactory. It is difficult to prevent the composition used from getting into the interstices of the edges of the glass plates, thereby endangering the purity of the bath, and producing a plentiful crop of pinholes.

In warm weather, if, instead of a stock being previously cleaned, a plate is polished just before it is wanted, the surface is rendered electrical, and it attracts all floating particles of dust, which is sure to spoil any negative taken upon it.

To remedy this, various substances have been proposed, but they have not found much favour, and photographers, as a rule, have been content to go on cleaning, polishing, and swearing, until tunicare made its appearance. Some photographers have succeeded with it, others failed; why I cannot tell, unless it is because it is not manufactured of uniform quality. I have tried it, but have not succeeded very well; seventy-five per cent. of the plates prepared with it were not useable, being full of dirty round spots and markings. I have tried different ways of cleaning before applying the tunicare, but the results were always the same.

On November 4th the NEWS had a formula in from a correspondent, that I determined to try, and the first batch of plates I prepared with it were all perfectly clean, and every batch since prepared has turned out good. So I have relinquished tunicare in preference for the following:—

Take the white of one egg, and beat it up well, and in a six-ounce bottle put one ounce of spirit of wine, two ounces of water, three drops of glacial acetic acid; to this add the albumen, and violently agitate the bottle, and then add three ounces of water, and allow to stand all night; in the morning filter the liquid from the curdled mass, and the filtered liquid is the preliminary coating. To use it, first soak the plates in cold soda solution, not too strong; rub

off the white deposit with a rag, and put into a weak solution of hydrochloric acid and water; then wash in five or six changes of clean water, and while still wet flood with the preliminary coating twice; stand up to dry upon clean white blotting paper, and when dry mark the wrong side, and put away for use.

Robinson's treacle process will be found very useful for preserving plates moist between developing and fixing, as three or four days may elapse between the two operations. I have used it ever since it was first published, and never met with a single failure. The plates, after three days, intensify as clean and bright as if only just developed. I use it precisely as first developed.

NOTES ON THE COLLODIO-BROMIDE PROCESS.

BY HENRY COOPER, JUN.*

IN proceeding to lay before the meeting the "Notes" I have prepared on the collodio-bromide process, I feel that some little preliminary explanation is due, both to the Society and to myself, with regard to the circumstances under which they are presented. I regret exceedingly my inability to appear personally on this occasion, for it would have given me great pleasure to have taken part in the discussion that will, I trust, follow the reading of this paper.

About eighteen months ago I determined to devote all the time I could get for photographic work to a careful series of experiments on the collodio bromide process, as I then thought, and still think, that in some form or other nearly all future dry-plate work would probably take this direction. Accordingly I set to work, and, by the end of our last session, my experiments had already furnished such satisfactory results, that I made a promise to the secretary that I would bring the subject before the Society; and I had great hopes that by the autumn I should have been enabled to do so, for, during the spring and early summer, I had been at work with encouraging success; but, unfortunately, in August last my health gave way, and I was compelled to give up entirely, and to leave London as soon as possible to spend the winter months here in Torquay.

When partially restored to health a great sense of disappointment came upon me: many of my experiments were not concluded, and I was quite unable to prepare any specimens for our exhibition in November. However, I had brought my "Note-book" with me, and, with the view of fulfilling my promise, I decided upon collecting such memoranda as seemed likely to afford help to others, and putting them together in the form of a short paper, suitable for reading at one of the Society's meetings. In so doing I must trust to the kind feeling and generosity of my fellow members to excuse many shortcomings. This kind consideration has been so often extended to me in bygone years that I have the greater confidence in asking my friends to overlook, on the present occasion, the want of absolute novelty in the following jottings. I have never hesitated to adopt the ideas of others whenever they have appeared to be of value, and I deem the thanks of photographers in general to be due to those gentlemen who, during the last two years, have so freely recorded the results of their experience for the benefit of all.

Of course, in a process like the collodio-bromide, which involves so many details at variance with our ordinary photographic practice, there is yet a very great deal to be learned, and I am truly sorry that my own investigations have been thus abruptly terminated for the present. From the experience that I have already had of the process, I am greatly pleased with it, and the points that particularly strike me are: the ease and celerity with

* Read before the Photographic Society of London.

which a large number of plates may be prepared; the great uniformity of every plate in a batch; the freedom from all worry about "baths and their diseases;" and, following from this, the greater ease of arriving a second time at certain determined conditions of success. Another important recommendation is, the good keeping quality of the plates; for those prepared in the manner I am about to describe have been kept for upwards of three months before exposure without any perceptible deterioration in the quality of the resulting negative, although I should think it necessary to slightly lengthen the period of exposure if more time than a fortnight were allowed to elapse between the exposure and development; but, on the other hand, I see no reason why my plates should not keep for much longer than three months before exposure, provided that care were taken in packing them. I may here mention that I regard plate-boxes as the worst things possible wherein to store dry plates for any length of time. Dr. Norris's method, or a modification of it, appears to be the most efficacious and convenient. With respect to rapidity, I may safely say that I have succeeded in preparing more reliably sensitive plates by the collodio-bromide process than by any other method.

I need hardly remind you of the great difference of opinion existing between Messrs Dawson and Carey Lea,—two most energetic workers with the process,—the one insisting that to secure success we must have an excess of soluble bromide in the film, the other that excess of nitrate of silver is advantageous. I do not feel qualified to judge as to which is the better method of working, as my experiments in that direction were not sufficiently conclusive; and I have, moreover, heard of others succeeding with either plan. I can only say that in my hands an excess of bromide has given decidedly the better result; and, judging not only from my own limited practice with this particular process, but from analogy, and our general experience of other photographic processes, in which an excess of nitrate of silver is employed, I can hardly help coming to the conclusion that films containing absolutely no trace of free nitrate would be far more likely to remain in good condition for a lengthened period. It must, therefore, be borne in mind that, in the method of working which I prefer, a certain proportion of soluble bromide is most essential.

It may often happen that, although there is an apparent excess of silver, such is not really the case, and this I have proved by actual experiment. When a quantity of nitrate of silver greater than is required to decompose the bromides has been actually dissolved in the collodion, no trace of the free nitrate could be discovered. Undoubtedly a portion of the nitrate of silver is taken up by the organic matter of the collodion itself, so that, although we may have adjusted the proportions of silver and bromide in their exact combining equivalents, the chances are that we shall really have some of the bromide still left unconverted. Mr. Bolton was the first to call attention to this important fact. I feel confident that, within certain limits, the more of this mysterious organic substance there is in the collodion, the more sensitive will be the film.

We may now proceed to the manipulatory part of the process.

First, as to the pyroxyline. Although it is undoubtedly better to employ a sample that has been specially prepared for this process, or, rather, one that is specially adapted for it, many collodions in the market may be rendered suitable by proper treatment. Those who have devoted much attention to pyroxyline know full well that the manufacture of this substance for any particular purpose is attended with much trouble and vexation if undertaken by one not accustomed to the work; and I feel compelled to depart from my usual plan, and to mention the fact, that the pyroxyline prepared by Messrs. Rouch is admirably adapted for the collodio-bromide process. I have

purchased it at different times during the past eighteen months, and have never known it to fail.* I will not detain you by dwelling upon my numerous experiments on the manufacture of pyroxyline, both from cotton and paper, and, as so many writers have fully explained the qualities necessary, need only say that I have come to the conclusion that the most suitable kind is produced by employing a maximum temperature, and a minimum of water in the acids.

So much depends upon the original character of the cotton, that it is almost impossible to give any formula that shall not require altering under some circumstances. I append, however, one or two from my note-book, with the remarks therein made upon them, as they may prove useful to those who intend devoting their attention to the manufacture of a suitable sample.

I must premise that I have prepared cotton many times by each of these formulæ, and have never failed in obtaining a product suitable for the collodio-bromide.

In each of them half of the quantity of nitric acid may be replaced by an equal proportion of commercial nitrous acid.

No. 1, A.

Sulphuric acid, sp. gr. 1845	...	8 fl. ozs.
Nitric acid, sp. gr. 1450...	...	4 "
Water	...	2 "
Cleaned and dried cotton	...	200 grs.
Temperature	...	150° Fahr.
Time of immersion	...	10 min.

No. 2, A. 150 grs. cotton immersed in same used acids, at a temperature of 120° Fahr., for 15 minutes.

Both gave pyroxyline perfectly soluble to the extent of 8 grains in each ounce of mixed solvents (equal parts alcohol and ether).

Fine adhesive films, very transparent and structureless. Gain in weight 30 per cent. in each case. Very good for wet collodion. Brilliant, intense, sensitive, and clean. No. 1, A slightly the better, being more fluid and powdery.

No. 12, C. Same proportion of acids and water as No. 1, A; but the temperature ten degrees higher. The cotton very nearly soluble. Very fluid collodion, with 6 grains to the ounce of solvents. Very adhesive and clean. Pours well, and sets well. Good for wet process.

No. 1, H.

Sulphuric acid, sp. gr. 1845	...	6 fl. ozs.
Nitric acid, sp. gr. 1450...	...	2 "
Water	...	1 fl. oz.
Cotton	...	100 grs.
Temperature	...	160° Fahr.
Time	...	10 min.

No. 2, H. Same proportions. Temperature 165° Fahr. Cotton powdery and short. Soluble. Not very adherent, but intense, sensitive, and clean.

(To be continued.)

ON LONG EXPOSURES IN CONNECTION WITH EXPRESSION.

BY EDWIN COCKING.†

ALL professional portrait photographers who have been called upon to produce negatives during the long-continued dull and foggy atmosphere in London and elsewhere must have occasionally been agreeably surprised by the capacity of some sitters to undergo the exceeding long exposure necessary to obtain a photograph at all.

Upon a recent occasion, being thus engaged, and whilst mentally counting time, after bestowing a sympathizing thought upon the patient individual behind us, who was

* There are so many photographers who might be induced to try the process if they can easily obtain a suitable pyroxyline, that I trust I may be excused from appearing to advertise a commercial article in this place.
† Read at a meeting of the South London Photographic Society.

made all taut by the useful body as well as head-rest, one's thoughts travelled back to the olden time, when Daguerreotype was the *modus operandi*, and we attempted to realize the fact that comparatively long sittings were then the rule, and not, as now, the exception. The results were, as regards expression, nearly all that could be desired. My experience arises, not from my own practice, but from having had occasion to procure Daguerreotypes of many persons, clergymen amongst others, for the purpose of producing from them a lithographic drawing for subsequent publication.

Whilst thus reviewing the past, I also recalled another fact, viz., that the operator (a well-known member of our profession) did not turn away from the sitter, but boldly stood his ground, and directed the thoughts, and, by well-chosen words and in gentle tones of speech, called up into the face of the sitter expressions which were afterwards found to be perfectly satisfactory by the friends who had to pronounce the verdict. Now, admitting this state of affairs, a long sitting is, after all, not a thing to be met with by a long face and a shrug of the shoulders, implying beforehand that we anticipate failure.

I have often, under conditions of light the most favourable, tried this experiment of looking at the sitter, and endeavouring to call up a cheerful or bright expression, but the rapidity of the taking was sometimes fatal to the result, as any alteration of the facial muscles was immediately conveyed to the sensitized plate, and a slight indistinctness was the natural consequence.

But that a *prolonged* sitting should be more likely to succeed seemed hardly feasible, when it was considered that possibly the continuous alteration of the muscles of the face during the sitting might produce a discordant effect. However, as it is the weakness of the chemical power which is the favourable cause of the ultimate success, lines or shadows on the face, being occasionally put out of the original position, become subdued and softened, and so all tend towards the desired object.

Another thing: the sitter, forgetting for the moment the real work going on in the camera, begins to lose the nervousness always in attendance upon the first few seconds of exposure, and gradually settles down into unconscious case.

Well, putting our recollections of bygone days into actual practice, we found that the sitters went through the ordeal with far better results than we had anticipated; but from the fact of having hitherto always been taken very quickly, and left to manage their own expression without being looked at, a certain amount of wonderment at the novelty for a second or two took possession of them, to be succeeded afterwards by a much more natural look, arising from not having their thoughts left to be centred upon themselves, or upon the utter blank in *sound* which the operation has always brought about.

I venture to draw attention to this subject, thinking that it may possibly induce others to try experiments in the same direction. The strong effects of light and shade, which will for the future demand the earnest attention of the art-photographer, involves the use of light in a more concentrated form, and, consequently, a slightly prolonged exposure must follow; under these requirements a field will arise wherein the experiment of influencing the expression will have ample scope for trial. Nothing is more trying and difficult than to produce *expression* through the agency of photography. Much depends upon the skill and manner of the artist, who, after trying all in his power to call up the desired expression on the face of the sitter, has then to leave him to himself, and trust to the power and rapidity of his lenses and chemicals to complete the work. But under the conditions of moderately long exposures, any alteration of the lights and shadows being also long in operating upon the plate, there will arise ample time and opportunity to suggest ideas and modifying the expression, should it tend to extremes either one way or

another. If the sitter is prepared beforehand, by stating that he is to be talked to during the exposure, he will not think much of the fact when it occurs.

I cannot help thinking that, in this direction, there opens up a field for investigation and trial well worthy of all those who have aspirations towards making our art science fulfil the requirements of portraiture to the very greatest possible extent.

Correspondence.

DISHES FOR DEVELOPMENT.

MY DEAR SIR,—In your excellent YEAR-BOOK Mr. England suggests the use of a dish for development of plates in out-door work. I think this will prove a most valuable suggestion for plates at all beyond the ordinary sizes. I should be greatly obliged to you or to Mr. England for information as to the *depth* of the tray inside, and whether he uses a spout in order to draw off the water. Of course, thorough washing is necessary between each plate—I am, &c.,
OXONIENSIS.

COMBINATION PRINTING-FRAMES.

SIR,—Few photographers will be surprised to find the validity of the patent of Edwards's combination frames questioned. I wrote to you in July (page 309, Vol. XIV.), pointing out not only the "outrageous" price Mr. B. J. Edwards asked for his frames, but my determination and ability to do without them. Mr. B. J. Edwards stigmatised my conduct (page 334) as "dishonourable," and apprehending that "but for the existence of such individuals, there would be no necessity for the Patent Laws, or the protection they fortunately afford to inventors."

Now the question is, Can Mr. B. J. Edwards be considered much of an inventor in this case? In the PHOTOGRAPHIC NEWS, page 17, Vol. X., is a description of a frame for opal printing, by Mr. F. W. Hart, very suggestive of everything.

Again, page 70, same volume, Mr. Geo. Willis gives another detailed description, securing the negative precisely as in the Edwards frame, and adding: "To secure the frame going back to its place when opened to examine progress of the printing, there are two hard wood pegs, and two holes for them to fit in."

Here is Mr. Edwards's *invention* again: Mr. Scales, page 35, Vol. XII., suggests the exact method of securing the paper, as adopted in Edwards's frame, in these words: "Leave depth enough of rabbit for thin piece of wood, round which I would double the sensitive paper to keep it in its place."

Again. The specification of a patent printing-frame abandoned by Mr. Field is given at page 127, Vol. XI., which ends thus: "A series of frames, similarly furnished with metal bearings and bow spring, is provided to fit in one another, to be used with negatives of different sizes." This disposes of Mr. Edwards's claim to originality with regard to interchangeability of frames.

Surely any man ordering a gross of frames to be made for him of a *certain* size can interchange them as much as he pleases without troubling about what Mr. Edwards considers his legal rights! Of course, Mr. Edwards has not found his specification all profit, although he has discontinued asking £2 2s. for a licence to use his frames. The mistake he made was not including all combination printing in his patent when he was about it.

Trusting that Col. Stuart Wortley will not only survive these terrible threats of law, but also the dangers to which he is exposed with Faidherbe's army, and still continue to favour photographers with his experience in your columns, I am, sir, your obedient servant,
INGENIO.

COMBINATION PRINTING FRAMES.

DEAR SIR,—In the last weeks NEWS I notice a letter from Col. Stuart Wortley in reply to one of mine previously published in another journal.

If, as Col. Wortley states, his frames were made before I called upon him in June last, perhaps he will kindly explain why he did not at once understand my method, supposing him to have completed a precisely similar invention, and why no reference was made to his frames at the time of my visit?

Col. Wortley's random assertion that my patent frame is a copy of Mr. Robinson's printing for opal glass carries its own refutation, the two frames being constructed for a totally different purpose, and being, as will be evident to all who have seen them, as unlike as possible in every respect, except that they are both made of polished oak.

The question as to the infringement of my patent by Col. Wortley will, in all probability, come before the Vice-Chancellor for decision. For the rest, the facts are as stated in my letter above referred to.

I am sorry to give you so much trouble in this matter, but in the interest of truth and justice I must ask you to publish this letter.—I am, dear sir, yours very truly,

Hackney, January 18th, 1871. B. J. EDWARDS.

DISSOLVING VIEWS WITH ONE LANTERN.

SIR,—In your last weeks NEWS, Mr. J. Martin appears as a champion for Mr. J. Powell, against the strictures of Mr. Baynham Jones and "Silvester," in reference to certain remarks made by those gentlemen regarding a plan of dissolving (?) invented by Mr. Powell. Mr. Martin says, "Does he (Mr. Powell) deserve insult for this?" I beg respectfully to state that no insult whatever has been given, and I am perfectly sure no insult was intended by either correspondent. The supposed insult and "untruthfulness" is the morbid offspring of Mr. Martin's imagination. The facts are these:—About three weeks ago Mr. Powell, through the medium of the NEWS, sought for an opinion as to the desirability of introducing a certain plan he had invented of producing dissolving (?) views with one lantern. One correspondent said, "Don't. Mr. Powell cannot have tried the plan before publishing it, or he would not, I am sure, have done so." The other writer informed him that "the scheme was an old one; that it was unsatisfactory; that the effect was unpleasant; and that the result was anything but approaching to dissolving." Mr. Powell publicly solicited an opinion regarding the merits of his plan, and also the desirability of introducing it to the public; and he obtained, through the same medium as he put the question, his answer. For what cause, therefore, has Mr. P.'s champion to complain?

How condescending of Mr. Martin to take Mr. Powell under his guardian care! But what quiet satire there is in his suggestion to Mr. Powell to "exercise his ingenuity in other directions, and I will render him any assistance through your pages!" How grateful ought Mr. Powell to be!

I ought to rebut the strange and subtle sophistries implied in the long tortuous sentence about "an idea," but your space would be taken up too much; but what a cruel thrust it also contains against putting faith in "obscure" pioneers of invention or science!

Mr. Martin says (though what reference it has to the matter in dispute I do not know), "Suppose some one tries to extract sunbeams from cucumbers; if he succeeded, he would be the greatest benefactor to photography ever known." (?) A happy thought suggests itself: could not Mr. M. attempt that? He would be sure to succeed.

I would refer Mr. M. to an amusing coincidence in last week's NEWS: it is with regard to his plan of using a "coloured glass over the nozzle of the lantern to produce the effect of being gradually lost to sight." If he will

kindly turn to p. 23, under the head "Talk in the Studio," end of third paragraph, it says: "Attempting to use pieces of glass is a very transparent error."—Yours truly,

January 14th, 1871.

SILVESTER.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY

THE monthly meeting of this Society was held at the Memorial Hall on Thursday, the 12th inst., the Rev. CANON BEECHY, M.A., President, in the chair.

After the routine business,

Mr. ROGERSON exhibited a large copying camera of very ingenious construction. One feature in this camera was much commended. The slide, instead of falling in a groove as in the ordinary construction, was made to rest upon bovils, which had the effect of keeping it always in its true situation, and yet allowed it to be removed with the greatest ease.

Mr. HEBERT said the plate-holder described in the *British Journal* of December 16th, page 589, was not very new; he had purchased just such an article about ten years since, and had brought it with him for the members to examine. It was much used at that time for suspending articles from the glass of shop windows.

A conversation took place on the preparation of collodio-bromide plates, the object being to ascertain how to prevent the formation of opaque spots in the film. The object was not attained.

It was decided that a lantern exhibition should form part of the proceedings at the next meeting, and that each member should have the privilege of introducing two friends.

C. ADIN, Hon. Sec.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held in the City of London College on Thursday, the 12th inst., Mr. J. T. TAYLOR occupying the chair.

The minutes of the previous meeting having been read and confirmed, the following gentlemen were elected members of the Society, viz, Messrs. William Mayland, J. Barnes, and James Tully.

Mr. EDWIN COCKING then read a paper "On Long Exposures in Connection with Expression" (see page 33).

The CHAIRMAN proposed a vote of thanks to Mr. Cocking for his paper, and regretted that, owing, no doubt, to the inclemency of the weather, the attendance was so small, for under usual circumstances a spirited discussion on the various topics suggested by the paper might have been anticipated. In portraiture, expression was very nearly everything; if that were good, numerous other defects would be regarded as of minor importance.

Mr. BARNES had found that permitting the sitter to talk during exposure did not interfere with the expression, but rather improved it, especially if the mouth were of an unpleasant shape.

Mr. FOXLEE asked what became of the beard, if the sitter spoke during exposure?

Mr. BARNES said that his remarks had special reference to ladies; the expression of gentlemen's mouths was of less importance.

Mr. FOXLEE found that a long exposure did not necessarily cause a bad expression on the face, for the lines of the face which, at the commencement of the exposure, were stiff, gradually became softened down, and a less rigid effect produced.

At this point the conversation became somewhat desultory, the topics of discussion being, among other things, the comparative rapidity of the Daguerreotype and collodion processes; tuning washed sensitized paper with ammonia; the advantages of "tunicare" as a substratum in the collodion processes, wet and dry. In reply to an observation by Mr. Hunter,

Mr. FOXLEE stated that the acetate toning bath, if made with hot water, would be ready for use in a very short time after its preparation; but when made with cold water it would have to stand over night before it was fit for use.

The proceedings then terminated.

Talk in the Studio.

PHOTOGRAPHIC POCKET ALMANAC.—Mr. D. H. Cussens has just issued his little pocket almanac for photographers. It contains much interesting and useful matter, and is a handy pocket volume of reference.

OPERATORS' SPECIMENS.—Another correspondent, signing himself "Swindled," complains of the non-return of the specimens he has sent in answer to advertisements, and which have not been returned, although stamps have been sent to pay the return postage. Our correspondent suggests that they are retained for exhibition as specimens. We do not think for a moment that such a motive has anything to do with the retention of specimens. It occurs at times, no doubt, from thoughtless carelessness and pre-occupation. It is often cruel to the operator, and altogether inexcusable, and, we believe, would rarely occur if thought were given to the subject. If operators would send a stamped and addressed wrapper for the return of their pictures, and always take care to place their names prominently on the specimens, we apprehend they would rarely lose them. The suggestions we have before made as to providing themselves with a few negatives from which to produce specimens would meet every difficulty, and if the name of the operator were scratched upon the film, it would appear in every print. The loss of specimens would rarely occur, and would be of little importance then, when it did.

PRELIMINARY COATINGS AND DRY PLATES.—Mr. W. T. Wilkinson, a correspondent who, a short time ago, spoke of the great advantage he found in a preparation of albumen, alcohol, acetic acid, and water as a preliminary coating, a mixture which he called "albumen tunicle," in a recent letter says:—"During the past dull weather I have not only perfected the preparation as a preliminary coating, but have also used it very successfully as a preservative for dry plates, and in such a manner as to entirely dispense with that stumbling-block to dry-plate photography, viz., washing the sensitive film. The mode of procedure is as follows:—A plate that has received a coat of albumen tunicle is collodionized and sensitized with the usual wet-plate chemicals, and upon withdrawal from the bath is flooded with albumen tunicle, recked to and fro to allow the tunicle to well permeate the film. Drain and dry as quick as possible. Fresh tunicle is to be used with each plate. The exposure, as far as I can judge at present, is about three or four times longer than wet plates, but probably it would be much quicker in bright weather. The development is effected by any of the dry-plate methods, viz., gelatine-iron and silver, acid pyro and silver, or alkaline pyro, and the resulting negative is very much like a gun-gallic plate."

PHOTOGRAPHIC SOUP.—The method of making a bowl of oyster soup that can be retailed for five cents, four of which will be profit, is as follows:—Take five Baltimore oysters, photograph them, to each photograph add five gallons of water, season to suit the taste.—*American Paper.*

PHOTOGRAPHY AND THE WAR.—A telegram in a daily contemporary says:—"A photograph of Fort Vanves, taken at a distance of several thousand paces, prevos the walls to have been much damaged by the cannonado."

To Correspondents.

B. F. D.—The imperfection of the tone of the prints enclosed in your letter is due rather to the negative than to any fault in printing or materials. The negative is wanting in vigour and contrast, being most probably fogged in the shadows. When this is the case the lights are printed through before the shadows are deep enough, and without deep printing you cannot obtain rich tones in the gold bath. With such negatives it is better to be content with brown tones, as in attempting to push the toning further, the tints become slaty and grey instead of purple or black.

ED. HOBBS.—The presence of iodide of silver necessary in the negative bath is most detrimental in the printing bath, always retarding or preventing the toning operation. If negative baths be employed for printing, the process of precipitating the iodide of silver by means of citric acid, which we have often described, should be employed. You will find one or two articles on the subject in our last volume.

J. A. D.—The account of the Woodbury photo-relief printing process given in the newspaper cutting you enclose is a fair and correct one. The only place at which you can get practical instruction is at the Company's Works, Hereford House, Brompton, where the process is in operation. The process is patented; whether licenses are issued, or at what cost, we cannot inform you.

A. Z.—The term "agreeable tones" is rather too vague to enable us to form an opinion as to what tones our correspondent desires. The colour of collodion prints is not nearly so completely under control as that of paper prints, the warm purple brown which is generally a favourite tint in the latter being rarely attained in collodion images, no matter how toned. As much depends, however, upon the original image as upon the toning. We have described various methods of producing and toning these prints; which does our correspondent employ? A new bath, full exposure, pyrogallic development, and gold toning produce good results, the tone being a fine black. The nitrate of uranium and ferrid-cyanide toning solution, mixed with a little gold, gives a purple brown. Mercury is a treacherous aid, but, followed by dilute sulphide of ammonium, it gives a good brown tone. The modified uranium intensifier on p. 114 of our Year-Book just issued will answer well for toning. 2. We do not know the address of any wig-maker.

N. CASINELLO.—We cannot speak with authority on your liability for taxation for a duly lettered vehicle used for business purposes, constituting dark rooms and conveying apparatus; but we should decidedly think that you are not liable, any more than a butcher or baker for his cart. Possibly some of our readers may be more familiar with the subject of taxation and liability, and may be able to give our correspondent information.

F. S.—The hyposulphite of soda solution is much less active in very cold weather than in warm weather. There is also always a considerable fall in temperature when hyposulphite is dissolved in water. It is wise, therefore, in winter to use warm water, or, at any rate, take care that the fixing bath is not used at a lower temperature than 50° Fah. It is well also to allow a longer time for fixing them in warm weather. 2. The use of a dipping bath for development has been tried, and has some advantages; but it has the disadvantage of diluting the free nitrate on the plate too much, and so rendering the negatives less dense. If you have tried it with success, there is no reason why you should abandon it.

A YOUNG BEGINNER.—Mr. Carey Lea enters into details of his mode of employing alkaline development in an article which you will find on p. 390 of our last volume (August 19th, 1870). It consists of pyrogallic acid and carbonate of ammonia used in different proportions according to circumstances, bromide of potassium being used as a restrainer. 2. Aqua-regia is a mixture of nitric acid and hydrochloric acid, two parts of the latter to one of the former. 3. We doubt not that you can get skiver of any dealer in bookbinder's leather; possibly you may get it of a book-binder.

L. F.—To produce collodion positives is not more difficult than to produce negatives; but some slight modifications are necessary. The nitrate bath should be acid with nitric acid; the collodion should contain not less than a grain of bromide to each ounce; the exposure may be a little shorter than that necessary for negatives; the developer should contain one or two drops of nitric acid per ounce, and is better when a few days old than when newly mixed. A point of the greatest importance is not to carry the development too far, but throw it off as soon as the principal lights have appeared. 2. Black varnish should not be applied to the collodion film, but to the back of the glass. Maroon velvet is more effective than black varnish.

T. D. R.—There is no fault in your reproduction of the engraving, except want of density. In reproducing such things in which the whites are pure white paper, and the blacks tolerably deep, much greater intensity is required than in most subjects from nature. If you have difficulty in getting sufficient intensity, try bichloride of mercury followed by dilute solution of iodide of potassium, and, if necessary, follow this by pyro and silver. Any degree of intensity may be so secured. The copy of an oil painting is less successful, probably because it involves greater difficulties. Being an old dark picture, you will find that it shows much more detail to the eye when its surface is wet; sponge the surface, and photograph it whilst the surface is moist. Use a freely bromized collodion, and give a full exposure in good light. Let us know of your success.

W. T. WILKINSON.—We have only time for experimental photography when the weather promises trustworthy results. We do not attempt it with such weather as we have had lately, the less so that we have always other pressing duties.

J. CUNNINGTON'S letter, and some other articles, stand over for lack of space.

Several Correspondents in our next.

A NOVELTY IN PORTRAITURE.

A PHOTOGRAPHIC novelty from the continent has recently been brought under our attention by Mr. Baden Pritchard, who has executed some portraits of his friends in the style to which we refer. This portrait is intended for use as a visiting card, for which the carte-de-visite was clearly neither intended nor fitted. Here a card, the size of a lady's visiting card, containing the name and address of the owner in the usual manner, has the top left-hand corner turned down—or, rather, ostensibly turned down—to receive a small medallion portrait on the triangular piece formed by the fold of the corner. The medallion is oval, about the size of a shilling, or less, and contains, of course, just the head and bust. The turned down corner, as we explained, does not actually exist; but the effect is gained by cutting off the top left-hand corner, and printing on the card the lines, forming a right-angled triangle, which the piece would form if turned down. At first glance, the effect is given of an actually turned down corner. The size of the triangular space formed is just sufficient for such a medallion as we have described, the base and upright of the triangle each being an inch and three-quarters long. In the examples before us the name, address, and lines are lithographed. The novelty is not, perhaps, a very important one, nor one likely to come extensively into vogue; but as the result is quaint and uncommon, it may please many, and, at any rate, is a thing easily tried; and any novelty which in any degree stimulates portraiture will probably be found a boon by any of our readers.

PHOTOGRAPHING CRIMINALS.

THE system of securing photographs of criminals with a view to identification, which has been in partial operation in Her Majesty's goals for several years, having been found productive of the best results in actually reducing the number of prisoners, and in aiding the just administration of the law by facilitating the distinction between habitual criminals and those who have only just placed their feet across the threshold of crime, was, in the course of last year, generally adopted in all prisons by order of the Home Secretary, acting under a clause in the Habitual Criminals Act. This measure, so simple, so reasonable, and so effective, both in its partial operation in this country, and in its more complete application abroad, was sure to meet with opposition from the maudlin school of humanitarians, and it has more than once been attacked as useless, tyrannical, and an interference with the liberty of the subject. Recently the *Daily Telegraph*, in an article devoted to a condemnation of the Habitual Criminals Act, declares that the "prison authorities have no more right

to compel a man who is simply awaiting his trial to sit for his photograph than they have to hang him"! It is not our province, in these pages, to discuss social or political problems, but simply to keep our readers informed on all points which affect photography and photographers; but we cannot help remarking, in passing, that it would be as reasonable to assert that the authorities have no right to arrest a man who is only accused of crime, and not proved guilty. The simple fact is, that laws are made for the protection of the community at large, and individuals merely charged with crime are always, of necessity, placed under disability and inconvenience. If a *prima facie* case is made out against them, then a means of identification for determining whether they have before come under the operation of the criminal law, or for reference should they be again found in a similar position, is surely one of the least offensive and most efficient aids to the effectual administration of justice, and hence to the preservation of the well-being of the whole community, which can be devised, and photography establishes another claim on the gratitude of society for its efficient aid in the matter. Here are the remarks of the *Telegraph* on the subject:—

Swayed by this idea [that the criminal classes are irreclaimable] two years ago or thereabouts, we armed our police with fresh powers of supervision, which have not added in any material degree to the security of society, whilst they have driven the criminal class to sheer despair. It may be said that the Act only applies to certain categories of offenders. We answer, that, in practice, it applies to all. Parliamentary sanction once given to spydom, it has leavened the whole mass. How is it that such an idea never occurred to a reasonable man as that all prisoners, committed to the House of Detention to take their trial, should be photographed, and the photographs used by the force? The prison authorities have no more right to compel a man who is simply awaiting his trial to sit for his photograph than they have to hang him. Any attendant or warder who meddled forcibly in such a matter might undoubtedly be convicted of assault, and would, no doubt, be punished in a very exemplary way. We simply give this as an illustration of our meaning. Let a man once fall so far under suspicion of crime that he is committed to take his trial, and straightway he is to be photographed, and his photograph is to remain as a "possession for ever" in the archives of the police. This second system—the clumsy idea of "once a convict, always a convict"—does not work well. It is as foolish as it is unjust. In a large measure the discretion of the judges and the magistrates has allowed the "Habitual Criminals Act" to remain a dead letter; had it been carried out to its full extent, it must have been already repealed. The Ordinary of Newgate does not sit down of set purpose to disparage the statute; what he does is to show us how "habitual criminals" are made. He asks us to assist, as it were, at the process of manufacture.

How far a knowledge that his photograph is in the hands of the police, to be used as a means of identification and increase of punishment should he again come within their clutches, should be an inducement to the criminal to become liable to arrest, we must leave to others to determine. It is clear that an honest man can

have no qualms of uneasiness from a knowledge that his photograph is accessible in case he is charged with crime. The evidence of the governors of gaols in which the system has been in operation for years is conclusive as to its efficiency in repressing crime, and thoughtless invectives against it, as interference with the liberty of the subject, are only worthy of a passing word in refutation.

PHOTOGRAPHIC SECRETS FOR SALE.

THE new American journal, the *Photographic World*, which, from advance sheets with which we have been favoured, seems to promise as much excellence as its elder brother, the *Photographer*, in the first number exposes the nature of certain photographic secrets which a photographer from Berlin offers to supply for the modest sum of a dollar and a-half. Herr Ritzler offers, in his advertisements, recipes for the following half-dozen desirable purposes, all, as he states, giving beauty to albuminized prints:—

“*First*.—To prepare the negative equal to any retouching that can be done, and especially adapted to tan, freckles, and red faces.

“*Second*.—To intensify any one part of a negative without interfering with the other parts—as one hand, one side of the face, &c.

“*Third*.—To make your paper, “after silvering, fuming, and drying,” give softness to the print.

“*Fourth*.—To prepare the hypo bath to give clear whites and light and rich draperies—splendid for Rembrandts.

“*Fifth*.—To improve the finish on your press, no matter what style of roll you use.

“*Sixth*.—How to make the “period,” or wreath vignette—the prettiest picture ever invented; can be made on plates; they will readily sell for double your card prices, and no extra expense in your work.”

A correspondent of the *World*, having forwarded a dollar and a-half and stamped envelope, received promptly a circular giving the promised recipes. As our readers will see, some of the hints are good, but not new; others are neither good nor new:—

“*First*.—After clearing, wash well, then pour a clean solution of gum-arabic over the negative, and let dry; with a soft pencil—using Indian red—rub carefully the face and hands: breathing on the plate will make the colour take; the heavier your colour the lighter your print.

“*Second*.—Develop, and let dry without clearing: cover all the parts but that to intensify, and using a sun-glass or back lens of your instrument, drawing the sun on the part until it blackens to your notion (do not heat the glass); then clear and varnish.

“*Third*.—Have your press clean, and roll your paper before printing.

“*Fourth*.—Add to a twelve-ounce bath one ounce alum and one drop to each ounce of equal parts alcohol and ammonia.

“*Fifth*.—Have the bed-plate moderately warm, and roll face down.

“*Sixth*.—Have a wreath size of quarter opening, cover an eight by ten cardboard with black velvet, and fasten wreath in centre; mark your ground glass the size you want, and have the copy of the inside of the wreath outside the work on ground glass, and expose; have another eight by ten covered with black velvet, and in the centre a quarter opening, and take the sitting through the opening, having the outside of the figure come to inside of work on ground glass.”

IMPURITIES IN NITRATE OF SILVER.

The editor of the *Photographic World*, referring to an article in a continental journal on the detection of impurities in nitrate of silver, recalls the fact that an examination made by a committee of gentlemen in New England satisfied themselves that the quantity of any foreign substance present in samples of nitrate of silver was so minute as to be scarcely

worthy of consideration. So far as our experience goes, the same fact is true of the nitrate of silver in this country. We have never met with a sample in which impurities could be traced to, or fairly ascribed to, wilful adulteration. Organic matter is occasionally found present as the result of insufficient care in the manufacture, and this the photographer knows may be eliminated by sunning in solution, or by means of a permanganate. Excess of nitric acid is the most common impurity, and may be removed by recrystallizing or fusing, or, sufficiently for practical purposes, by neutralizing. Nitrate of potash, the most easily added adulteration, we have never found present in any sample; its presence would be injurious chiefly because it would cheat the purchaser in the cost, and deceive him as to the true strength of his solution. The method of detecting it suggested by Herr Kruger, and quoted below, is very simple. Although, from infrequency of adulteration, means of detection do not possess vital importance, and are known to many photographers, it may not be uninteresting to quote the remarks of the continental contemporary referred to:—

“Silver which has been obtained from photographic residues contains generally only two impurities—iron and copper; the former mechanically, the latter as an alloy. When, however, we wish to enumerate all the bodies with which nitrate of silver is adulterated in order to increase the profits of the chemist, we must mention the nitrate of bismuth, lead, and potassium, particularly the latter, for it is extensively used for this purpose.

“It is not difficult for the practical photographer to detect these impurities. The colour, the manner in which it breaks, and the manner in which it dissolves, will indicate the presence of iron, bismuth, or saltpetre.

“Iron imparts to nitrate of silver a yellow colour. Saltpetre gives a concentric fracture in the form of rays; and the fused sticks will dissolve unequally, and become honey-combed. Bismuth is indicated by making distilled water appear milky when the nitrate of silver is dissolved in it, caused by the formation of an oxide of the nitrate of bismuth. Copper is detected by adding ammonia to the nitrate of silver solution, and if the latter turns blue, copper is present.

“Saltpetre (nitrate of potash) is also easily detected by the following method:—A piece of nitrate of silver weighing about eight grains, or a stick of about one-eighth of an inch in length, is placed upon a clean plate of glass or a saucer; it is touched with the still glowing part of a burnt match, when it will burn immediately, and when chemically pure, a residue of metallic silver will remain. The residue is placed upon a piece of red litmus paper, and moistened with a few drops of distilled water. When the silver was chemically pure, the paper will retain its colour unchanged; but when the nitrate of silver had been adulterated with saltpetre, the paper around the residue will assume a blueish colour, more or less intense, caused by the caustic potash in the residue. This experiment is very easy, requiring no apparatus or preparation, and its results are perfectly reliable.”

THE NATURE OF DIFFERENT GUMS.

DR. SACC, of Neuenburg, Switzerland, has made an extensive inquiry into the nature of different resins. The *Photographic World* condenses from it the following results. The resins spoken of are: copal, amber, dammar, common rosin, shellac, elemi, sandarach, mastic, and Caramba wax. All these resins can be reduced to powder.

The following will become pasty before melting: amber, shellac, elemi, sandarach, and mastic; the others will become liquid at once.

In boiling water, Caramba wax will melt; common rosin will form a semifluid mass; dammar, shellac, elemi, and mastic will become sticky; while copal, amber, and sandarach will remain unchanged.

Dammar and amber do not dissolve in alcohol; copal becomes pasty; elemi and Caramba wax dissolve with difficulty; while rosin, shellac, sandarach, and mastic dissolve easily.

Acetic acid makes common rosin swell; on all the others it has no effect.

Caustic soda readily dissolves shellac; rosin partly; but has no influence on the others.

Amber and shellac do not dissolve in sulphide of carbon; copal becomes soft, and expands; elemi, sandarach, mastic, and Caramba wax dissolve slowly; while rosin and dammar dissolve easy.

Oil of turpentine dissolves neither amber nor shellac; swells copal; dissolves dammar, rosin, elemi, sandarach, and Caramba wax easily, and mastic very easy.

Boiling linseed oil has no effect on copal, amber, and Caramba wax; shellac, elemi, and sandarach dissolve in it slowly; while dammar, rosin, and mastic are dissolved easily.

Benzine does not dissolve copal, amber, and shellac; elemi and sandarach to a limited extent; Caramba wax more easily; while dammar, rosin, and mastic offer no difficulty.

Petroleum ether has no effect on copal, amber, and shellac; it is a poor solvent for rosin, elemi, sandarach, and Caramba wax, and a good one for dammar and mastic.

Concentrated sulphuric acid is indifferent to Caramba wax; it dissolves all resins, imparting to them a dark-brown colour, excepting dammar, which takes a brilliant-red tint.

Nitric acid imparts to Caramba wax a straw colour; to elemi, a dirty yellow; to mastic and sandarach, a light brown; it does not affect the others.

Ammonia is indifferent to amber, dammar, shellac, elemi, and Caramba wax; copal, sandarach, and mastic become soft, and finally dissolve; while rosin will dissolve at once.

It is not difficult by means of these reactions to test the different resins for their purity.

DEVELOPING DISHES.

BY WM. ENGLAND.

In answer to the request of your correspondent, "Oxonensis," in the last week's NEWS, the following hints may be of service. The dishes for development may easily be made in the following way:—Make a thin frame of wood, say one and a-half inches in depth, mitred at the corners, and with a groove running round half an inch from the bottom. Before putting the corners together, cut a piece of sheet glass to the size of the frame, and place it in the groove; after which the mitred corners may be fixed together, using for this purpose a tolerably thick solution of shellac; the same also should be poured round the groove where the glass has been fitted, to prevent leakage; and, finally, varnish the wood-work with a more dilute solution, applying two coats if necessary. Dishes made in this way last for years with proper care. They must be thoroughly washed after having been used. It will be found necessary to have several trays approximating to the different size plates used by the operator.

A dish for development is not, as your correspondent mentions, a suggestion merely, but a mode of development practised by me during the past twelve years, and which I have found of great service working in a tent and during hot weather, and in all cases where a difficulty may be found in making the developer flow evenly. To amateurs I would strongly recommend it; it saves the hands from being stained, and, what is of more importance, a cleaner and more perfect result is obtained.

To those not having any experience in its use permit me to offer the following hints on removing the plate from the dark slide:—

Place it in a dish (film upwards, of course), and take rather more than the quantity of developer usually used, and pour, with one sweep, over the plate; immediately rock the dish with a steady motion, to cause the solution to act evenly over the whole surface. In this way no fear need be entertained of markings from unequal development. When the image appears fully developed, pour the solution, by the corner of the dish, back into the measure, and, on holding the former up to the light, the glass bottom permits the operator readily to see if the development has been carried on sufficiently. Should this not be the case, the solution may be re-applied. Those in the habit of intensifying with iron may do so without removing the negative from the dish. If, instead, the operator prefer pyro, it is necessary, after well washing the plate (which may be done in the dish) on its removal, to affix it to a holder, or hold it in the hand, and proceed in the usual way.

ASTRONOMICAL PHOTOGRAPHY IN AMERICA.

BY DR. VOGEL.*

BESIDES photographs of the Pleiades, I also saw pictures of the Bootes with Arcturus, obtained with an exposure of six minutes. The development of these star pictures is conducted with a strong iron solution, made up of twelve parts of water to one of iron.

One special task which Rutherford has set himself is the daily reproduction of the sun. A small photographic apparatus fitted to his telescope, in which the eye-piece is employed as enlarging lens, yields an amplified picture of the solar disc, measuring some 77 millimetres, or nearly three inches, in diameter. The opening and closing of the lens is brought about by the passing over of a small slit by means of a spring, similar to the method improvised for taking instantaneous views. The duration of exposure in these sun-pictures is one five-hundredth of a second.

The pictures thus secured daily by Rutherford are particularly sharp and well defined, and show plainly the spots and markings upon the sun's disc; and in examining a series of them, taken one day after another, one can see plainly how the spots advance in their position as the sun rotates, and how they also become enlarged or modified in shape, &c. In one row of pictures in my possession, which were taken daily between the 11th March and 14th April, there may be seen the several large spots appear on the east edge of the sun, traverse the whole surface of the disc, and disappear at the western edge, to reappear again, after the lapse of about twelve days, at the eastern edge in perhaps a somewhat modified form. As regards the value of these pictures, and what they teach in respect to the rotation of the sun and the size of the spots, we need make no special comment; Rutherford's results represent the history of the great luminary as written down by nature itself.

One marked peculiarity in all of these sun-pictures deserves mention—the circumstance, viz., that the margin of the image invariably appears darker than the middle. This is an important consideration, as a similar effect is also observed in reproductions of partial eclipses of the sun, when the inner arc always appears much more brilliant than the outer margin. This may be explained from the circumstance of the developer being poured on always from the one side; but such a reason will scarcely hold good, as in the American photographs the solution was not invariably applied in the same manner. The effect is due rather to the chemical action of the sun's rays being less on the margin of the sun's disc than in the centre.

An entirely different method of photographic astronomy for solar observation was to be seen at Cambridge (Boston). At the observatory there, there had been erected a horizontal metal tube, B, measuring some forty-two feet in length. At the front end of this was fixed a six-inch

* Continued from p. 32.

achromatic lens, L, having a focus of forty feet. At the back of the tube, at H, a photographic camera was fitted inside a room, the lens having a diaphragm of an inch and a half; the tube was protected from the weather by a roof, and rested upon a structure of solid brickwork.

For the purpose of obtaining a photograph of the sun, a heliostat, S, was fixed upon the pedestal, P, and the mirror of this instrument reflected the sun's image into the lens at L. The lens yielded a direct picture, without enlargement, measuring four and a half inches in diameter, upon the photographic screen at H. The exposure was regulated

in a very simple manner: a plank, Q, having a slit one inch in breadth, was drawn quickly across the lens from top to bottom, and, as the slit passed over the stopped-down lens, the exposure took place. Instantaneous exposure was quite sufficient in this case also.

An arrangement of this kind has many advantages over that of the moving telescope; it yields a much larger direct picture, and necessitates but very simple optical appliances; moreover, no complicated mechanism is necessary for the accurate movement of the apparatus, which not unfrequently becomes thrown out of gear. This latter defect is of especial importance in scientific expeditions.

As one of the most recent results of American photography, we must refer to the taking of pictures of the protuberances in full sunlight, to which we alluded on a former occasion. It is true the result obtained is not a perfect one; but, nevertheless, it is of the highest importance, as proving the possibility of performing such an operation. This astronomical feat was performed by Professor A. Young, of Dartmouth College, with the assistance of Mr. Bly, a photographer, of Hanover, New Hampshire. A spectroscope with seven prisms was, after removal of the eye-piece of a parallax telescope, screwed upon the same in a suitable manner; the telescope had an aperture of 6.4 inches, and a focus of nine feet, the object-picture being about one inch in diameter. A portion of the sun's limb, projected upon the slit of the spectroscope, gave a spectrum picture, in which the protuberances were represented by single bright lines. At the eye-piece of the spectroscope was placed a small camera, six inches in length and one and a quarter in diameter, upon the focussing screen of which the eye-piece (as in the case of Rutherford's arrangement) rendered an image of the lines. (By the way, it is not stated which of the lines were focussed.) The telescope was set in motion by clockwork, which, unfortunately, did not work very regularly, and the result was, therefore, not very clearly defined. The exposure allowed was from three and a half to five minutes, the chemicals and solutions employed being those in ordinary use.

It is to be regretted that it was impossible, at the time, to repeat the experiment with better means and apparatus, as the telescope which served to obtain the results was required for the purposes of the recent eclipse, and had to be sent off at once, with a party of astronomers, to Spain.

Only two of the lines shown in the pictures are of a bright character, and these to the extent of but two or three millimetres. The distortion of the lines is very remarkable, and is due to the imperfection of the lens employed in their reproduction. The same defect was to be noticed in Rutherford's pictures, taken in the same manner, viz., by means of the eye-piece of a telescope. This instrument is not designed for photographic purposes, but merely for ocular observation, as, indeed, its name implies; and it is no wonder, therefore, if it fulfils imperfectly any other use to which it may be put. Only the

very centre of the image can be relied upon as correct, if the eye piece of a telescope is made to do duty as a photographic lens; and it is far better, where a registered result of this nature is required, to employ an instrument specially corrected, as in the case of the Steinheil lens, used by the Aden eclipse expedition.

ON FLUORIDE OF SILVER.

BY GEORGE GORE, F.R.S.*

THIS paper contains an exhaustive account of the behaviour of argentic fluoride in vessels of platinum, carbon, and various fluorides in contact with chlorine, bromine, and iodine at various temperatures. When argentic fluoride is completely decomposed by chlorine in platinum vessels at a red heat, the reaction agrees with the following equation:—

Vessels of cryolite and of fluor spar were found incapable of retaining argentic fluoride in a melted state. Other vessels were also made by melting and casting various mixtures of earthy fluorides at a high temperature; and although forming beautiful products, probably capable of technical uses, they were not capable of retaining silver fluoride in a state of fusion. Numerous vessels were also made of seventeen different fluorides by moulding them in the state of clay and baking them at suitable temperatures; these also were found incapable of holding melted fluoride of silver. Argentic fluoride was only superficially decomposed by chlorine at 60° F. during thirty-eight days. When heated to 230° F. during fifteen days in a platinum vessel in chlorine, it was very little decomposed. Chloride of silver heated to fusion in a platinum vessel in chlorine corroded the vessel and formed a platinum salt, as when fluoride of silver was employed.

An aqueous solution of argentic fluoride agitated with chlorine evolved heat and set free oxygen, in accordance with the following equation:—

or—

Dry hydrochloric acid gas completely decomposed argentic fluoride in a melted state, but only acted upon it superficially at 60° F. A saturated aqueous solution of argentic fluoride was not precipitated by chloric acid.

Perfectly anhydrous fluoride of silver was only superficially decomposed by contact with bromine in a platinum vessel during thirty-six days at 60° F., or during two days at 200° F. At a low red heat, in vessels of platinum, argentic fluoride was completely decomposed by a current of bromine vapour, a portion of its fluorine being expelled and a portion corroding the platinum and forming an insoluble compound of fluoride of platinum and bromide of silver. In carbon boats at the same temperature the whole of the silver salt was converted into bromide, the boat being corroded and the fluoride escaping in chemical union with the carbon. The action of bromine on an aqueous solution of argentic fluoride was similar to the action of chlorine. A solution of argentic fluoride yielded copious precipitates both with hydrobromic and bromic acids.

Under the influence of a temperature of 200° to 600° F. in closed platinum vessels, iodine very slowly and incompletely decomposes argentic fluoride without corroding the vessels and produces a feeble compound of argentic iodide, fluorine, and iodine, from which the two latter substances are expelled at a red heat. At a red heat in platinum vessels, iodine produces argentic iodide, and in the presence of free argentic fluoride corrodes the vessels in consequence of formation of platinum fluoride; iodine and fluorine pass away together during the reaction. In vessels of carbon at the same temperature argentic iodide

* Abstract of a paper read before the Royal Society.

is formed, the vessels are corroded, and a gaseous compound of fluorine and carbon is produced. By treating an aqueous solution of argentic fluoride with iodine, similar results are produced as with bromine and chlorine; a similar solution yields copious precipitates both with hydriodic and iodic acids.

A mode of analysis of iodine is also fully described in the paper. A known weight of iodine was dissolved in absolute alcohol, a strong solution of argentic nitrate of known strength added to it in portions at a time, with stirring until the colour of iodine exactly disappeared. The mixture was evaporated, the free nitric acid expelled by careful heat, and the residue weighed. The residue was then heated to fusion, to convert the iodate of silver into iodide, and again weighed. Two experiments of this kind yielded accurate results, and the process was easy and expeditious.—*Chemical News.*

A FEW ITEMS WORTH REMEMBERING.

BY JOHN C. BROWNE.*

DRAINING GLASS PLATES.

A VERY simple and excellent plan for draining glass plates is to drive nails into the wall or partition of the dark-room, and cover them with tight-fitting rubber tubing, which can be cut into the exact lengths required, and easily adjusted. The head of the nail prevents the plate slipping off, and, by varnishing the rubber, all liability to staining, which sometimes occurs from iron-rust, &c., will be avoided.

VARNISHING.

To obtain a good coating of varnish upon the negative, allow the greater part of the varnish to flow off the plate as is usually done, then reverse the drainage by turning the plate up side down, and give it a gentle rocking motion to prevent lines of drainage. This may be done to advantage by resting the plate upon several folds of tissue-paper. Apply the varnish in a warm room free from drafts and dust. It is well to brush the film, before applying the varnish, with a wide camel's-hair gilder's brush, using great care not to injure the surface by rough handling. Do not drain the varnish back again into the bottle from which it was poured, but have a wide-mouthed bottle ready for that purpose. Plates varnished as described will be free from dust and floating particles, and present a uniform surface which protects the negative perfectly.

CUTTING AND MOUNTING PRINTS.

These final operations are too often hurried over as matters of but little consequence, and photographs that otherwise would be perfect, are seriously damaged by not being cut straight in trimming, and afterwards carelessly mounted. It is a good plan, in trimming prints, to use pieces of plate glass cut to the required size, having the edges ground accurately; by this means the picture can be cut perfectly straight and with great rapidity.

Cleanliness in mounting is absolutely necessary, otherwise the photograph cannot present other than a slovenly appearance. Use good fresh paste for this purpose. (I prefer gelatine.) If it is necessary to introduce any substance to preserve it in warm weather, add a few drops of carbohic acid; but paste made fresh each day is much more reliable. In mounting, be particular to press down the edges of the print on the card, and make due allowance for the expansion of large prints, if mounted after they are dry, for wetting them with paste causes the paper to expand very much. Adopt, if possible, a cardboard having a lithographed space in the centre, so that there will be a sufficient margin of the oil tint outside of the edge of the picture. The tint adds much to the appearance, and undoubtedly preserves the photograph from the action of hurtful chemicals often to be found in the mounting cards.

After mounting, roll the picture several times under heavy pressure. Some advocate that the finished picture be

rubbed over with a composition of wax, lard, camphor, &c., with a piece of cotton or wool, the advantages claimed for it being that the pores of the paper are closed, thereby preventing atmospheric and local influences; but if put on too thickly, which is often the case, marks are made in handling the print which are very perceptible. A card, rolled under pressure sufficient to give a brilliant surface to the photograph, is, in my judgment, more desirable than treatment with wax, &c.

CHLORIDE OF PALLADIUM FOR TONING GLASS POSITIVES.

Now that slides for the magic lantern are so much sought after, the best method of printing and toning such pictures is of considerable interest. In the treatment of glass positives that require additional contrast after fixing, many chemicals have been suggested, and, after a careful trial of their merits, I am disposed to consider chloride of palladium as the most reliable chemical that has come under my notice. Its action is perfectly manageable, easy to prepare, will not stain, and gives uniformly good results. The toning solution that I use is made as follows:—

Add six drops from the stock bottle of chloride of palladium to each ounce of water; this solution should be of a delicate straw colour. No other manipulation is required. After the plate has been developed and fixed, wash as usual, then apply the toning solution by flowing it over the plate similar to the developer. Its action will be quick, giving a black tone to the positive. Wash well, dry, and varnish if desirable. Allowance must be made, in toning, for the kind of light to be used in the lantern; the oxyhydrogen, magnesium, and electric lights require that the positive should be made more dense than for lanterns depending upon coal oil for illumination.

TO REPAIR LEAKY DIPPING BATHS.

Baths that are composed of glass and rubber very often give great annoyance by leaking, and from my experience with a small dipping bath attached to a Nelson Wright box, I almost gave up the idea in despair ever to make it hold nitrate of silver. After repeated disappointments with both patching compounds, I tried a solution of gutta-percha in chloroform with good success, as the bath is now perfectly tight. At first I was unsuccessful with this mixture, as the attempt was made to apply the solution with a brush, but afterwards several ounces of this solution were poured into the bath (which had previously been allowed to dry perfectly), then by turning it so that the solution should remain for some time on each corner or joint, the chloroform evaporated, leaving the gum in quite a perceptible deposit all over the joints. After that, the bath was found to hold silver, and has not shown any signs of leaking for over a year.

NOTES ON THE COLLODIO-BROMIDE PROCESS.

BY HENRY COOPER, JUN.*

In preparing the bromized collodion, great care must be taken to have the solvents of good quality. Pure alcohol of sp. gr. 805, and purified and rectified methylated ether of 730, are required.

Alcohol of 825 is also needed; but unless the commercial article is proved to be very good, it is better to dilute the absolute alcohol with distilled water to this strength.

The formula for the bromized collodion is as follows:—

Ether, sp. gr. 730	4 fl. ozs.
Alcohol, sp. gr. 805	2 "
Bromide of cadmium	40 grs.
Bromide of ammonium	24 "
Pyroxyline	from 40 to 50	"

In mixing, the bromides must be first dissolved in the alcohol, the ether added, and, lastly, the pyroxyline. As

* *Photographic World.*

* Continued from p. 33.

soon as thoroughly settled it is ready for use, provided the pyroxyline have been of suitable quality. With an ordinary cotton the collodion will require keeping for some time in a warm and light place to ripen.

I shall, however, presently show how a new collodion may be made to give satisfactory results, even when it is not specially adapted for the process.

We now come to the quantity of nitrate of silver required to form the emulsion of collodio-bromide. You will all doubtless remember the discussion that arose last spring as to the combining equivalent of bromide of cadmium. It is undoubtedly true that sufficient notice has not hitherto been taken of the fact that commercial bromide of cadmium contains a variable quantity of water of crystallization. And so large a quantity does it usually contain (four equivalents), that unless this be taken into consideration, we may make some egregious mistakes in compounding the emulsion. If no objection be made to the slight extra trouble, it is a great advantage to thoroughly dry the bromide of cadmium before use, so as to drive off this tiresome water of crystallization by means of heat, or by enclosing the bromide in an air-tight vessel for some time with some substance specially greedy of moisture, such as dry chloride of calcium. If the bromide be submitted to gentle heat for a few hours until it becomes white and powdery, we may conclude that it is rendered practically anhydrous.

I think that a still better plan in future will be to use the double bromide of cadmium and ammonium, which is anhydrous, and does not readily absorb moisture from the air. Some persons have objected to its use on the ground that it was not yet ascertained whether only single equivalents of each bromide went to form the double salt, and that, therefore, we were employing a salt with the constitution of which we were not thoroughly acquainted. In the case of some of the other double iodides and bromides recently investigated, it has been found that sometimes two eqs. of one salt is united with one of the other, or in other variable proportions. I naturally feel great diffidence in expressing an opinion on the subject; but my own experiments have pointed to the conclusion that, in the case of the double bromide of cadmium and ammonium, the two salts are united in single equivalents.

Fortunately, however, there is a practical method of making use of the good qualities of the double salt without allowing any uncertainty to creep in.

The mode of proceeding is to weigh 172 grs. of freshly crystallized bromide of cadmium ($\text{Cd Br} + 4 \text{HO} = 172$), or 136 grs. of the anhydrous salt ($\text{Cd Br} = 136$), and 98 grs. of bromide of ammonium ($\text{NH}_4 \text{Br} = 98$). Dissolve the two in a small quantity of distilled water, and very carefully evaporate to dryness. Finally, powder the dry salt obtained, and preserve for use in a well-stoppered bottle. Use 64 grs. of this double salt instead of the separate bromides in the collodion.

If the collodion be bromized with this double salt, or with dry anhydrous Cd Br, $10\frac{1}{2}$ grs of pure nitrate of silver will be required for each 6 fl. drs. of collodion, so as to leave a proper proportion of bromide unconverted. If crystallized bromide of cadmium have been used, $9\frac{1}{2}$ grs. will be sufficient.

As regards the mode of mixing the silver and collodion to form the emulsion of collodio-bromide, I am decidedly of opinion that it is far better to dissolve the silver in alcohol and add it to the collodion, than to adopt the early method of merely grinding it up with the alcohol in a tube mortar and gradually adding the collodion thereto. There are many reasons for this, but I will only mention one or two. In the first place, by absolutely dissolving the nitrate of silver we run no risk of leaving small particles unconverted, and thus we are not only more certain of having the proper quantity of the bromide present, but the collodion is much sooner fit for use.

Again, the bromide of silver is formed in a much finer

state when the nitrate of silver is added to the bromized collodion than when the process is reversed. Had I been present I would have exemplified this by pouring a solution of nitrate of silver into one of bromide of cadmium, and then pouring a solution of the bromide into one of silver, and allowing you to compare the two results.

The third reason I shall mention is the fact that, when the alcohol and silver are added to the bromized collodion, there is no danger of precipitating any of the pyroxyline; at least, the chances of such an occurrence are reduced to a minimum.

Now, in employing the other method, I have many a time been mortified to find the pyroxyline and bromide thrown down in stringy looking lumps. This is caused, as you will readily perceive, by the first portions of collodion poured into the mixing mortar becoming so diluted by the alcohol as to render the solvents unable to hold the cotton in solution; and when once this precipitation has occurred, the collodion will generally have to be put on one side as useless, as, owing to the pyroxyline and bromide going down together, it is well nigh impossible to redissolve the former and diffuse the latter.

Before describing my mode of preparing the emulsion, I must call your attention to one or two other points.

It is generally acknowledged by all workers with collodio-bromide, that the emulsion becomes very much more sensitive by desensitizing and keeping before again adding nitrate of silver. The oftener this sensitizing with silver and desensitizing with fresh bromized collodion is repeated, so much the more sensitive does the film become, until at last, as the maximum is reached, fog begins to make its unwelcome appearance. By always saving the residual collodion after preparing a few plates, desensitizing, and then adding the proper quantity of silver when another batch is to be prepared, this sensitiveness of film is readily obtained. But then comes the trouble that no two batches are equally sensitive, so that here a most undesirable element of uncertainty is introduced. I have, therefore, discarded this way of working. Again, it is a useful axiom to remember that, everything else being equal, the more *creamy* the film the more sensitive it is to light. This brings us to another point worthy of remark. If the bromide of silver be formed in the presence of an excess of nitrate of silver, the film produced by the emulsion is much more creamy than if it be produced in presence of excess of bromide. You will remember that I have already said that, at the moment of using the emulsion, the bromide must be in excess.

I have dwelt slightly upon these several points here, so that you may the more readily understand the *rationale* of my method of mixing the emulsion without further explanation. What I had to accomplish was to produce a collodio-bromide that should give the maximum of sensitiveness and opacity of film, combined with general constancy of result.

To do this, I proceed in the following manner:—Measure 12 fluid drachms of bromized collodion into a four-ounce bottle. (We will suppose that the collodion has been bromized with anhydrous bromide of cadmium, or with the double salt. If the crystallized bromide has been used, the quantity of silver must be altered.) Carefully weigh 32 grs. of finely powdered pure neutral nitrate of silver, and, without losing a morsel, convey it by means of a strip of paper, folded lengthwise, to the bottom of a clean test-tube. Pour upon it 3 fl. drs. alcohol 825, and raise it to the boiling-point over a spirit-lamp, occasionally shaking the tube round and round, so as to disperse the particles of silver throughout the spirit. When cooled down, pour off the dissolved nitrate from the few remaining particles into the 12 drs. of collodion, little by little, agitating the mixture two or three times meanwhile. Now boil the remainder of the nitrate in the test-tube with 3 fl. drs. more of alcohol until completely dissolved, and add it to the emulsion in the same manner as the first quantity.

You will notice that as I have taken sufficient nitrate of silver to sensitize 18 drs. of collodion, and mixed it with only 12 drs., that the nitrate is considerably *in excess*. After standing for a few hours, 12 more fl. drs. of collodion are to be added, and the mixture well shaken. We have now the *bromide* in such excess (there being 24 drs. of bromized collodion, and silver only for 18 drs.), that the emulsion will keep uninjured for a very long time. When required for use, 10½ grs. of nitrate of silver and 2 drs. of alcohol are to be added; and after standing at rest for about an hour the collodion is ready for the immediate preparation of the plates. No filtering is required. Of course it is not at all necessary to sensitize the whole of the collodion at once. One-half or any other quantity may be taken, and a proper proportion of nitrate of silver and alcohol added to it.

One of the great advantages of this mode of preparing the emulsion is, that a large quantity can be made up at one time; and the amount of silver requisite to be added to a given quantity having been calculated and marked on the bottle, we have a good working collodion always ready for use. By adding the silver in excess in the first instance, we not only obtain a good creamy film, but the combination of the silver and organic matter of the collodion (previously referred to) is the more readily formed, and extra sensitiveness thereby obtained.

(To be continued.)

Correspondence.

CARBON PRINTING V. SILVER PRINTING.

DEAR SIR,—Your consistent advocacy of carbon printing having extended over a long series of years, I have no reason to complain of your adverse commentary on the remarks I offered in reference to that mode of photographic reproduction which you have so faithfully and, I might add, so ably defended whenever its qualifications have been brought into question. You will, however, admit that the tenor of your remarks imperatively recalls me to the front to act on the defensive as best I can. My inclination would have been better suited by a less conspicuous antagonist; nevertheless, as your pen has drawn me into the controversial arena, I hesitate not to accept the challenge by at once putting my friendly lance in rest to argue, with honesty of purpose, and without fear or favour, in defence of the views I advisedly entertain respecting the subject now at issue, trusting that the result of the contest may work good to photography.

Your first objection I am unable to answer as I would wish, for, unfortunately, I am, in the most essential particulars, bound down to silence; otherwise I could a tale unfold which would prove all sufficient to drive conviction home to the minds of the most sceptical that my conclusions are based on something more substantial than an insufficient evidence or a fallacious estimate of evidence adduced from observation and hearsay. Honour, however, leaves me sufficient material to work out the object I have in view, which consists of a desire to elicit the truth; and nothing but the truth will satisfy my endeavours.

[To secure brevity and the absence of repetition we will, as shortly as may be, add our answer to each point as it arises. Our position was, and is, not simply that Mr. Bovey's evidence was based on hearsay, but that all the evidence in existence at present is insufficient to support his conclusion, the trial being as yet too limited.—Ed.]

The principles on which the various forms of carbon printing are grounded have for years been, to myself, an earnest study; and although I candidly admit that my experience is not strictly practical, yet I flatter myself that I am sufficiently acquainted with the working of each carbon process to detect its weak points without any serious tripping over of my power of judging.

[It is very easy to detail the weak points of any process, but a conclusion based on such detail must obviously be erroneous. This is our objection to Mr. Bovey's conclusion. A correct estimate must include strong as well as weak points, which Mr. Bovey's did not.—Ed.]

In reply to my statement that carbon printing has been tried and found wanting, you express your impression that there are *not* half a dozen portraitists in the United Kingdom who have tried the process on a commercial scale. But does this assertion aid your case? [Yes; it proves the process has not been tried.—Ed.] As a man of business, you must admit that a process of such alleged value could not have been overlooked by photographers, whose special characteristics have been to err in an opposite direction to that of indifference. Can you believe it possible that the process has not been tested by more than the number who have undertaken the work on a commercial scale? Doubtless prudence has, in a hundred cases, dictated the necessity of the preliminary test, experiment; and yet, by your own showing, there are *not* half a dozen persons who practise the process commercially! What does this, by inference, prove? Simply that "carbon printing has been tried, and found wanting"! Were I at liberty to mention names, I could, on more reliable grounds than inference, show that the process has been tried by some of the most able exponents of photography, and they, at least, have satisfied themselves that the Autotype does not answer for general print production—that it cannot occupy the place of silver printing. [Two or three experimental trials are not test in any satisfactory sense, nor could the results of such trial form any fit comparison with the silver prints produced by trained skill. To give this evidence any value, it should be specific, not general. The nature of the tests upon which conclusion has been made should be stated, and the names of the witnesses. We know of none who have made trial and found carbon printing wanting.—Ed.] Would A. Salomon, Mr. Robinson, Blanchard, or any one who is qualified to rank with these master portraitists, consent to stake their great reputation on carbon printing as a sole mode of production from their negatives? I challenge a reply to this query. Would either of the gentlemen I have named or alluded to hesitate one minute to adopt a permanent process if such process was, in practice, as capable as the doubtful system necessity compels them to retain? Their well known devotion to their art elicits the reply: "I trow not."

[If general evidence be inadmissible and inconclusive, still more is hypothetical evidence valueless; nay, rather does the production of assumed evidence, not based on fact, suggest the non-existence of actual evidence of any real weight. M. Adam Salomon and Mr. Blanchard have not tried carbon printing. Mr. Robinson has or is doing so, and doubtless his evidence will be forthcoming when he himself thinks it right or desirable to give it; but we cannot admit assumed evidence as of any weight whatever. If these gentlemen hold the views ascribed to them by Mr. Bovey, they doubtless will, when they think proper, express them with their own explanations. Until then their names can have no place in the controversy.—Ed.]

Your fourth paragraph opens with an assertion that I have admitted the superiority of carbon prints taken off a good negative. In point of fact, I have made no admission in the direction from which your view is taken, although the absence of an explanatory context makes your error quite natural. The superlative I applied was comparative with carbon, *not* with silver; the remark simply implied that carbon prints from "show negatives" are *superior* to the many hundreds of carbon proofs that surrounded me in the room where the conversation to which I made some allusion occurred.

[We drew the natural conclusion from the words. It would be easy to adduce evidence to prove that with ordinary good negatives carbon prints can scarcely be distinguished from silver. At the Photographic Department of

the Royal Arsenal, for instance, where carbon has been adopted, this is the case.—Ed.]

For argument sake, I will, if you please, admit the somewhat paradoxical point that the imperfections of Autotype are due to its finely balanced perfections; in other words, the imperfections of carbon printing arise from an inherent defect in the process; but they owe their being to the damaging uncertainties which beset negative production. Were all negatives perfect, the Autotype could command an equality of perfection. My concession, however, affords no aid to a final settlement, as it must be allowed that physical and chemical conditions intervene to make it a matter of absolute impossibility to produce negatives of uniform excellence. Where one really good negative is produced, there are at least fifty, on an average, taken that range from indifferent to moderately good, no matter whether the operator be a captain or a lieutenant of his art. And what inference may we draw from such a fact? Why, that no printing process can be accepted as commercially practicable that is incapable of neutralizing the defects to which negatives are, without the possibility of alteration, subject. You, sir, with much candour, admit that in some instances a carbon print taken from the same negative is not equal to one produced in silver; but you attribute the shortcomings of the former to a want of the requisite experience on the part of carbon printers. In point of actual fact, the silver process, although known during the period you state, was not extensively practised prior to the years '59 and '60. It has certainly enjoyed a large patronage since those dates were current; but the perfections of silver printing are due to the labours of comparatively few among the multitude of practitioners, and these were in no case blessed with the pecuniary aid which the Autotype has received.

[For the first twenty years of its existence silver printing was probably practised by a hundred times as many, and for the last ten years by a thousand times more, than carbon printing has been in the six years of its existence. All workers contribute, in a greater or less degree, to forming the status of a process.—Ed.]

In your case, curiously enough, you concede a broad position in your remarks respecting the paucity of workers in carbon, and your statement "that a greater familiarity with the possibilities of the carbon process will probably produce equal skill in humouring faulty negatives," goes to show that the carbon process is not a tried process—ergo, it is not a perfected process—because a larger number of workers are needed to develop its capabilities. But is it possible to make the process practically perfect?

[It is certainly not, in any complete sense, a tried process, and, probably, by no means a perfected process. In all ordinary probability, each skilled worker who takes it in hand for some time will make it more perfect in some point; but in the balance of qualities we think it is more perfect than silver printing now; but it requires skill and experience to work it successfully.—Ed.]

You must remember that silver printers dodge in the light, and on this point lies the chief value of the method; whilst carbon workers must dodge in darkness. Would a Salomon like to undertake such a task?

[When the occasion arises we have no doubt means will be found.—Ed.]

If carbon printing has lacked helpers, it most certainly has not wanted for those better sinews, funds. One firm alone has expended more pounds on the process than I should care to count against time. Why, I hesitate not to assert that a twentieth part of the sum spent would set me up in heliotype printing on an extended scale; and I would stake my existence on the results of printing being equal to anything the carbon process is capable of yielding under the most favourable conditions.

[As no one yet has produced prints by any of the photographic processes equal to the ordinary run of good carbon prints, Mr. Bovey's pledge must remain in abeyance until we see his work in this direction.—Ed.]

Your statement that the Autotype Company are working profitably, and biding their time for a wider development, which they expect, and are preparing for, but do not care to hasten, has a dash of romance about it which cannot be overlooked. Why do they continue to advertise so industriously, and to push their process in every possible direction? But you reply, the process has never been pushed. I readily admit that Mr. Swan did not personally push his invention. He probably had a higher game in view; but there were, at all events, no lack of pushers devoted to his cause, even though there has turned out a paucity of labourers to engage in the perfecting of the pushed and puffed process. Holloway himself might have envied the pushing Autotype has been subjected to. The advertisement pages of the photographic journals teem and have teemed with efforts to push carbon printing. The same pages have made public the wranglings of rival inventors in a manner more curious than instructive.

Oppositionist has hurled threats of legal proceedings against opposition, who, in turn, quoted law, whilst it was quite apparent that both parties feared to take action. In behalf of Autotype, dozens of leaders, supplemented by scores of contributed articles and letters, have appeared in the several journals devoted to photography, and, in addition to these supports, the process has entire publications devoted to its interests. The most influential of the daily press has recited in its praise, and several of the industrial serials have joined in the laudation. Yet, with all these formidable aids to commercial progression, "carbon printing, has not been pushed"! If such be so, I am certainly at sea in my definition of the verb to push as applied in a commercial sense. Vested interests must, indeed, constitute a barrier more stout than even a battalion of Prussians, or it must long since have yielded to such a pressure. But can it, I ask, be vested interests only that oppose themselves against an alleged valuable process? If so, the obstructive power of those interests have no parallel in the annals of commerce, except in cases where parochial bumbledom thrust its stupidity in the way to block progress. History certainly records instances of long struggling efforts to push useful inventions into notice; but, as a rule, the struggling ones floundered in that bog of neglect, which poverty generates. Autotype knows no such experience, as it has never lacked funds to back its efforts.

[We repeat our statement that, except by journalists discharging their duty in proclaiming aloud that permanent printing is possible, carbon printing has not been pushed. The quarrels of inventors and patentees are not aids to pushing, but really repressive, and have deterred many from engaging in a process which might involve them in possible litigation. The advertisements are just such as ordinarily intelligent men of business employ, and certainly are neither excessive in quantity nor puffing in verbiage. The amount of capital expended is in all cases, we believe, found to be a good investment, a fact which proves success, not failure.—Ed.]

In conclusion, I desire that it should be distinctly understood, in the event of this discussion being continued, in order that the subject might be kept within comprehensive bounds, I have no wish to deny the ingenuity displayed in the disputed process, neither do I call into question its exceptional adaptability for the reproduction of such subjects as Brauu has made his speciality, as both stand unquestionable. My sole object is to see decided, once and for all, whether the carbon process is capable of occupying the place of silver printing. I have no attachment to old methods, no vested interests I value before progress, no feelings of conservatism to interpose objections. Let it be clearly proved that carbon printing is better than I believe it to be, and I at once recant, and shall enrol myself among its most ardent admirers. That you might be in a position to offer such proofs is the desire of,—Yours truly,

W. T. BOVEY.

2, Charlton Villas, Park Road East, Acton, W.

[In the absence of new facts a discussion of this kind results in little beyond the expression of opinion, or of conclusions from facts known to the public, who, after all, will form their own conclusions on the evidence. At present the great element of time and experience is wanting. An established system in full work, and upon the working of which incomes and the maintenance of families depend, will not be easily uprooted by another until perfect assurance is attained that it will not peril those incomes in any degree. The mass of photographers naturally wait for the experience of the more wealthy or adventurous. This will gradually come; until it does come—and it is, as we know, in formation—decided opinion on the capability and fitness of carbon printing for general work is premature, and prophecies of failure at once foolish and unfair.—Ed.]

DISSOLVING VIEW LANTERN FOR PHOTOGRAPHIC SLIDES ONLY.

DEAR SIR,—I have been much interested in the correspondence on the above subject, but am sorry to see it leading to such useless controversy, instead of tending to solve the problem. May I, with all humility, offer to your notice the following plan? Of course it will not do for lever slides, &c.

Instead of the slide-holder being made in the usual manner, let it be so that the slide can be inserted like the dark slide or focussing screen of the camera; let there be two grooves in close contact, like the grooves of a plate box. Instead of the pinion head for focussing, have a small winch, and if the tube is a little longer than usual, so much better. Have, also, a long wire pinion from the lamp through a small hole in the lantern side, so that the light can be raised or lowered without opening the lantern-door. Aftershowing the picture, turn the winch till quite out of all focus, gradually lowering the light at the same time; then gradually lower the next picture in the empty groove, and raise out the other one; turn back the winch, and also the light; and that's all.

Another Plan.—Instead of lowering the light, get a large vignetting glass about 5 by 4, cut the opaque portion from one end, and glue it on the other opaque portion, so that it will be double; place it in a wood or tin frame, fitted only at both sides and on the opaque end, where it should be hinged to the bottom of the lantern; this should be flat when not in use. To use it, have the pinion wire about two inches longer at the opposite end from the winch; on this have a barrel, to which attach a cord of proper length; pass the cord through a hole at the top of the lantern, and fasten it to one corner of the frame of flashed glass. After a picture has been shown by turning the focussing winch, you dissolve the picture in two ways at the same time by putting it out of focus and excluding the light.

I do not know if I have been sufficiently explicit, but I think if some manufacturer would take up the subject, a dissolving view lantern would find a good sale.—Faithfully yours,
WILLIAMS.

PIRACY AND COPYRIGHT.

SIR,—As some of your scientific correspondents begrudge the space given in your columns for the discussion of copyright, let me remind them of its close relation to the honesty and morality of a large portion of the photographic trade. Where a portrait photographer produces one picture, the illustrator of a book produces a hundred, and the scrap dealer a thousand. Wherefore, the discussion of the right and wrong of this trade is of as much practical value as a debate upon the eccentricities of an acid or the haziness of a film.

I shall be glad if the author of "Echoes of the Month" will, in his next communication, point out some of my "manifest errors." Let me remind him that in order to prove the creation of an artistic copyright, it is only necessary to show, in the case of a painting, drawing, or photograph, that the provisions of the first section 25 and 26

Victoria, cap. 68, have been observed; and, in the case of an engraving, that the name of the proprietor and date of publication have been truly engraved upon the plate, and printed upon every print. There may be fifteen Acts of Parliament relating to various kinds of copyright, literary, sculpture, engraving, paintings, and designs; but my letters relate directly only to one, viz., the Artistic Copyright Act, and only incidentally to one other, viz., Hogarth's Act. I have not said that the whole of the law of copyright is simple, but only that the conditions upon the performance of which copyright can be claimed are simple; and I must repeat, that they can scarcely be made more simple. I am surprised that the lengthened experience of "An Old Photographer" has not shown him how wide-spread and important are the industries concerned in this question of what may or may not be done in photographic copying.

Now that various methods of printing in carbon have been perfected, without question an immense impetus will be given to the trade in reproductions of works of fine art, and it is of consequence that those who embark their time and capital in that trade should know precisely how they may be affected by the operation of the law of copyright.

"Justitia" says, "I know nothing of the law of copyright beyond what I have learnt from this correspondence;" and then, with feminine haste, jumps to the conclusion that the law is "miserably uncertain and perplexing." Will "Justitia" read the first sections of the Acts 8, Geo. 2, cap. 13, and 25 and 26 Victoria, cap. 68, and then say what he finds there to be perplexing. My arguments refer only to the conditions necessary to be observed in order to obtain copyright, and not to the whole law of the subject, which is beside the matter we are discussing. He adds: "As it was never denied that these copyrights had been dearly bought and honestly paid for, and that, therefore, they ought to be inaccessible." I have never had occasion to deny the truth of that novel proposition, but will do so now. "Justitia" surely does not mean to maintain that copyrights ought to be inaccessible because they are "dearly bought," and for that reason men who infringe them should be sent to prison whether the conditions of the Act have or have not been complied with. I can hardly think this to be his meaning, because a little further he observes that it would be in the highest degree wrong to send such men to prison. Upon that point we agree. Perhaps he means that the proprietors should render their copyrights inaccessible by complying with the provisions of the statute; but, as he justly remarks, they, through "sheer stupidity," fail to do so. That copyrights are "dearly bought," I do not admit. Artists will tell "Justitia" that publishers are keen at driving a bargain. That copyrights are "honestly paid for" is open to question, and I will state a case in illustration. A lady painted a certain charming picture, from which a popular engraving has been made. This picture, while upon the easel, she sold, without the copyright, to a picture dealer for £60, who paid to her a deposit of £5. The picture was exhibited, and was seen by a publisher, who wished to purchase it. He bought it of the picture dealer at an advanced price, upon the understanding that he should pay to the artist, on behalf of the dealer, the sum of £55, making, with the deposit of £5, the sum of £60, the original price of the picture. This money was paid to the lady by two instalments. When she received the last instalment, the publisher placed before her a receipt for her signature, stating the total amount as being for picture and copyright. The lady objected to sign, and wished to know why copyright was mentioned in the receipt. The publisher assured her that it was perfectly regular, and that the copyright always went with the picture. The lady then signed the receipt. At that time she was the registered proprietor of the copyright. Will "Justitia" think that the copyright was "honestly paid for," or will he think, with me, that it was an immoral proceeding on the part of the publisher? Although I object to moral platitudes in a legal discussion as being perfectly useless, elsewhere I do

not object to morality. "Justitia" writes of "some people whom Mr. Cunningham defends," meaning thereby pirates. In my letters I have only attacked the legality of certain convictions; and surely "Justitia" will allow me to do that without imputing to me a desire to defend piracy. I admit "law to be the means and justice the end of jurisprudence," but I cannot admit that the Copyright Act defeats its end. Let "Justitia" prove that. If it does, so much the worse for the legal reputations of Lord Westbury and Sir Roundell Palmer, who are generally considered to be able lawyers.

As regards "the judge and magistrates," with the exception of "Colonel" Burke's case, no question of validity of copyright under the Act of 1862 has been brought before a judge. "Justitia's" assertion that certain photographs exhibited in a shop window defeat a righteous law, is a non-sequitur. A work of art is either copyright or non-copyright; if it be copyright, a piratical copy will not defeat the copyright; and if it be non-copyright, a copy of it, if it be immoral, is certainly not illegal, and, therefore, does not defeat the law.

It is also open to question whether a publisher of engravings has any moral right to protection under the Act of 1862. He has a legal right in some instances, and yet it is certain that the Legislature never intended him to have that. The Act is intended, *inter alia*, to prevent the illegal copying of paintings, drawings, and photographs. When it so happens that the publisher of an engraving is the owner of a copyright of the painting from which the engraving has been made, and an illegal copy has been produced from the engraving, he has the power to sue under this Act, not for piracy of the engraving, but for piracy of the painting, a copy made from the engraving being necessarily a copy of the picture; but the mischief contemplated by the Act is the direct copying of pictures, drawings, and photographs by means *ejusdem generis*. That such was the intention of the Legislature is evidenced by the 8th section of the Act, which provides that any pecuniary penalty incurred pursuant to any Act for the protection of copyright engravings may be recovered under this Act. The penalty under the Engraving Act for each piratical copy is five shillings.

Soon after the Act passed, proceedings were taken to recover five shilling penalties; but as the case was tried before a magistrate at Bow Street who possessed a logical mind, and who did not desire "to crack the nut and get quickly at the kernel," he took time to study the Act before giving his decision. When he did so he dismissed the summons, in consequence of certain words having been omitted in the Engraving Act, at the same time pointing out to the complainant that he had a remedy in the County Court.

The offence provided against by the statute is that of making illegal copies of paintings, &c.; the penalty for each illegal copy is not to exceed £10 by summary conviction, and it is not inflicted so much by way of punishment upon the offender, as by way of recompense to the complainant, the amount not being payable to the Crown, but to the person aggrieved. It is, therefore, the duty of the magistrate to ascertain what is the probable loss occasioned to the complainant by the particular Act charged, and to amerce the defendant accordingly. When the loss to the complainant amounts to £1, it is unjust on the part of the magistrate to inflict a penalty of £5. That this view of the law is reasonable is, I think, shown by the remarks of Lord Chief Justice Erle, who, in trying a case where two defendants were charged with selling three illegal photographs, and in which the plaintiff's counsel urged the jury to give exemplary damages because his client had suffered much from piracy, said, in his charge, that he entirely disagreed with the arguments of the plaintiff's counsel; the defendants were before them to answer for what they themselves had done, and not for the acts of other people. All that had been proved against them was that they had sold three

photographs; he thought the damages should be moderate. The jury returned a verdict with £1 damages in each case.

The administration of the law is anomalous. Piracy can only be punished on summary proceedings by a pecuniary penalty. The magistrate can only order imprisonment upon non-payment of the penalty. But persons have been arrested on warrants, and thus been subjected to imprisonment before any offence had been proved against them, a proceeding evidently antagonistic to the spirit of the law. Warrants have also been granted without any sworn information having been first made; for that, however, the magistrate is responsible. When the Copyright Act passed, the Small Penalties Act was not in existence. Magistrates then sometimes inflicted the full penalty of £10. In default of payment there was no power to imprison; the penalty could only be recovered by a warrant of distress. After the passing of the Small Penalties Act, by reducing the penalties to £5, magistrates obtained the power to imprison for non-payment for a period not exceeding two months in each case. But the operation of the Act only extends to England, therefore in other parts of the United Kingdom piracy cannot be punished by imprisonment.—I am, sir, your obedient servant,
J. CUNNINGTON.

London, January 10th, 1871.

FADING OF PRINTS.

SIR,—In the last number of the NEWS Mr. Bovey has a paper on "Autotype Printing, and a few hints on the causes which affect the permanency of silver prints." May I ask if the principal reason for the fading of many silver prints is not to be found in the wretched remuneration doled out to photographic printers. I really believe there is not a man so employed in this city who gets more than £1 per week; this is considered a high rate of wages; the usual rate is from 5s. to 10s. per week. How can it be expected that such miserable pay will induce persons of any chemical knowledge whatever to undertake such work as photographic printing? Apart from this, I do not think the fading of prints (I am speaking of portraits) is of such importance as many articles in the papers would lead us to suppose. How often are photographers called upon to produce prints from negatives three or four years old? Fashion in dress varies so continually in the present day, that every one must be taken in the newest rig: this is fortunate for the photographer. In this city most of the photography is carried on by persons having other businesses. The proprietors have no knowledge whatever of photography themselves, but merely engage operators, printers, &c., to do the work; and the fading of prints which would be heartrending to a Williams and Mayall is passed by, in this happy land, with the greatest composure. So long as a printer can get off so many sheets per diem, it matters not much how they are done, so long as they are got out of the house. I do not think the public care much about the prints in their possession turning a bit yellow; they take it for something akin to the mellowing of paintings by time; and certainly not during my experience as a printer for many years do I ever remember a print being complained of on account of fading. I believe that carbon printing is a grand advance in the art, and is of the highest importance in fixing indelibly the images of great worthies, scenes, &c., &c., but for general work I fancy silver will do well enough.

I now wish to trouble you, sir, with one question on a subject which comes directly home to me.

If an employer who is not a photographer himself, and has scarcely ever seen a number of the PHOTOGRAPHIC NEWS, takes apprentices, am I, as a printer, bound to instruct them without premium, so that, as soon as they are able to do in some way or other, I am discharged to make way for the young recruit?—I am, sir, yours obediently,
P. MURPHY.

Dublin, January 22nd, 1871.

POSTAGE OF PHOTOGRAPHS AND INVOICES.

DEAR SIR,—Enclosed I beg to hand you copy of letter to Post Office, and their reply, by which it is shown that one can send *photographs* and an *invoice*, if weighing less than two ounces, for a halfpenny. To show that this is not generally known, only last week I received three cartes from an eminent publishing firm, postage one halfpenny, and invoice per letter post, postage one penny. The two would have come for the halfpenny.

Enclosed carte (a trifle flat) is an example of long exposure, being over one minute, during which time conversation was kept up.—Yours faithfully,
ARCHER CLARKE.

To the Postmaster-General.

DEAR SIR,—Your reply to following three questions will oblige:—

No. 1. Is string allowed round packet containing cartes-de-visite?

No. 2. Is an invoice allowed enclosed in packet containing cartes-de-visite?

No. 3. Are cards allowed for halfpenny postage, the same not being a post card as issued by the Post Office?

REPLY—C134780.—Stourbridge.—To inform the applicant that a book packet containing photographs may be fastened by means of string in the manner shown in the specimen.

[Note.—Two strings were used, one round and one across.]

An invoice *strictly* such, and bearing no communication of the nature of a letter, may be enclosed in a book packet.

He should also be told that, except in the case of circulars intended for transmission in *identical terms* to several persons, no card other than one of those issued by the Government will pass under a halfpenny stamp, if it bear on it a written communication of the nature of a letter. See page 14 of the British Postal Guide.

PHOTOGRAPHIC RAMBLE IN A VAN.

SIR,—I and a friend wish to make a short photographic tour in Ireland during the summer months, and we are thinking of traveling in a gipsy or travelling photographer's van. We believe that this mode of photographing has been tried before; and we would thank any of your correspondents who have done so, to inform us as to whether their tour proved successful, and how they procured the van—whether bought or hired.

A few hints as to how it was fitted up would also be very acceptable.—Yours truly,
W. G. C.

2, Warrior Terrace, Hastings.

COMBINATION PRINTING-FRAMES.

SIR,—I beg to thank "Ingenie" for his letter in your last.

I must again say, that my principle is quite different from Mr. Edwards's, and far less costly.

Mr. Edwards has only to refer to my letter in the NEWS of the 6th to find the explanation he asks for.

I have the best legal advice as to Mr. Edwards's patent being quite worthless.—Yours, &c.,
H. STUART WORTLEY.

Talk in the Studio.

SUBSTITUTE FOR YELLOW GLASS.—As a substitute for yellow glass in the dark-room, Mr. Fr. Hangk recommends common window glass which has been coloured on one or both sides yellow with collodion prepared in the following manner: 30 gram. Pernambuco wood are covered with 180 gram. absolute alcohol, and 60 gram. ether. This is left to digest for a few days. The liquid is now decanted and digested with 2½ gram.

gamboge. After a few hours this is to be filtered, and sufficient pyroxyline (about 10 gram.) is to be added, so as to form a rather thick collodion. The liquid is poured on the glass, and care must be taken to keep the plate as nearly as possible in a horizontal position while the collodion drains off. When it has become dry, the opaque film is to be covered again with the same collodion, leaving out, however, the gamboge. The glass is then ready for use. Annatto or saffren may also be used for colouring collodion yellow; but all organic bodies of this kind should be examined from time to time, as they generally lose the adiacinic colour.

A WATERPROOF COMPOSITION.—Dr. Scherzer, an Austrian official at Pekin, has just sent to his government some specimens of a Chinese composition called "Schiociao," which has the property of making wood and other substances perfectly water-tight. He says that he has seen in Pekin wooden chests which had been to St. Petersburg, and had come back uninjured, and that the Chinese use the composition also for covering straw baskets, which are afterwards employed in carrying oil for long distances. Cardboard, when covered with the composition, becomes as hard as wood; and most wooden buildings in Pekin have a coating of it. It consists of three parts of blood deprived of its fibrine, four of lime, and a little alum.—*Eastern Budget.*

SHAM BANK NOTES.—According to the latest information, the hoax of counterfeit sovereigns is only the last of a series of transatlantic swindles on the same principle. The United States notes were first imitated. Circulars were sent to almost all the business men in the States, offering thousands of dollars' worth of such imitations at a charge of one-tenth of the nominal value. A guarantee was given that the notes would be perfect facsimiles of the real thing, every letter, line, dot, and mark being right. When the dishonest fly fell into the spider's web and sent his money, he received in due time a mysterious package. The imitation of the notes was perfect, but they were only one-third of the right size, being, indeed, nothing else than photographs of real notes. This business flourished bravely for some time, as, of course, the victims were not the men to publish their own shame.—*Observer.*

PHOTOGRAPHY AND THE PIGEON POST.—In an article in the *City Press* of Jan. 1, the writer, after remarking that it is estimated that one pigeon can carry 15,000 messages, and that the public have yet to learn the particulars of their condensation, arrangement, and transit, concludes by saying that "no doubt photography on silk is the proximate agent, as, without question, the pigeon is the ultimate agent."

IODIDE OF SILVER IN ITS PHOTOGRAPHIC-CHEMICAL RELATIONS.—In a paper in the *Polytechnisches Journal*, Dr. J. Schnazs points out that there exist two modifications of iodide of silver one of which is actinic—that is to say, sensitive to light—while the other is not so. The author also points out that iodide of silver is very soluble (up to equal equivalents) in a solution of nitrate of silver, forming therewith a double salt, AgO,NO₃+AgI, which, if the solution of the nitrate is quite neutral, is far more sensitive to light than either of the two salts by themselves.

PHOTOGRAPHY AND THE DIPLOMATIC CONFERENCE.—The *Telegraph*, referring to the fact that other important Congresses have formed the subjects of interesting paintings, remarks:—"At the first blush there would not appear to be much that was favourable to the picturesque element in a Conference. The painter called upon to portray the assemblage of so many dignified Plenipotentiaries met to discuss political questions, might reply that he would as soon delineate the characteristics of a banking-house or a parliamentary committee-room; and that, if mere portraits were desired, the subject was one more for photography than for fine art." The writer then proceeds to speak of pictures of such conferences which have acquired historic interest. These have been produced by painters. In many respects, however, the future interest of such pictures will depend more on the precision of likeness than on pictorial effect, always difficult to secure in such groups. Mr. McLachlan's large photographic group of the Committee of the Cotton Famine Fund, and the groups of members of the British Association, are admirable examples of what may be done in this way, and we doubt not that a worthy photographic representation of the members of the Diplomatic Conference would possess an interest for the future scarcely inferior to that which could be secured by a painting.

To Correspondents.

ADVICE TO CORRESPONDENTS.—We are at all times glad to advise our readers on any subject connected with the art upon which information can be given in this column; but to enable us to do so with efficiency, and without unnecessary waste of time and space, it is desirable that a few conditions should be observed by correspondents. All questions should be stated clearly, and written legibly on sheets of note paper, small scraps of paper and sheets of foolscap being equally unsuitable and inconvenient. Where several questions are asked, they should be kept distinct and numbered. Where processes and formulæ have been stated in our pages, it is better for correspondents to refer thereto than to request us to do so, as we cannot, with fairness, occupy space by repeating formulæ which have once appeared, merely to save a little trouble to individuals. Correspondents should use distinctive names or initials: such signatures as "A Subscriber," "An Amateur," and others of a general character being often adopted by a few correspondents in the same week leads to confusion.

OWEN CHESTER.—As different opinions prevail amongst high authorities, it is difficult to say which is the best dry process. The gum-gallic process, about which you enquire, is a very excellent process. 2. A preliminary coating of one grain of india-rubber in an ounce of chloroform is recommended by Mr. R. Manners Gordon. It is applied by flooding the plate as with collodion. 3. Plates should be dried by heat; a drying-box is useful for the purpose. These boxes are made in various ways. A tin-lined box heated with gas is useful for the purpose. 4. Mr. Gordon, who has experimented most extensively in the process, finds that plates prepared as he instructs will keep for months. You will find full instructions in the YEAR-BOOK you have just received. 5. There are many articles on the subject of micro-photography scattered through the whole of our volumes; but in many cases they are on especial points of the subject. For instance, there is very excellent information on the use of the magnesium light in micro-photography on pp. 320 and 330 of our last volume. There are some good practical articles on the general subject in our Seventh Volume. There is a useful little pamphlet on the subject published by Cox, of Ludgate Hill.

J. H. WOOLLEY.—The plan you propose appears excellent, and will, we have no doubt, answer well. There will be no need for glass on the south side. White screens for reflection will, at times, be useful; and, in some instances, quartering the head round a little towards the light, placing the sitter and camera cross-cornerwise of the room, will be useful.

ONE WHO WISHES TO LEARN.—The heads you enclose are lighted a little too directly from the front, or, rather, with too much front top light. A little more side light is desirable. A profile is generally more effective when lighted partially from the side and back of the head. Otherwise, the work has much promise.

OXONIENSIS.—We do not know whether the use of ground glass for negatives has been much adopted. It is only ground on one side, and the negative is taken on the polished side. We presume that any photographic dealer will supply ground glass suitable for the purpose; either plate glass or crown would answer. We doubt whether the result is worth the trouble, although it undoubtedly produces a little softening. Try it for yourself. No method of this kind will produce the same effect as retouching the negative. The latter involves the use of intelligence, such portions being touched, and such defects, coarsenesses, and rugosities being removed as interfere with truth or beauty in the picture. A mechanical method merely softens all portions alike, without selection. Perhaps the best of these methods is that which Carl Meinerth has so well carried out under the name of photo-mezzotint. It consists in printing with direct sunlight, with a piece of thin glass between paper and negative. 2. We do not know much of B personally, but, from what we learn, we believe A to be the best and most rapid.

ENQUIRER.—Make the transparencies the same size as the original, or, rather, enlarge them a little. Nothing could be gained by reducing them, but something must be lost, because in that case the physical defects due to possible structure in the collodion film of the transparency, or granulation in the deposit forming the image, will suffer in proportion to the extent of the amplification. A good portrait lens well stopped down, or a rapid rectilinear, will answer best.

H. S.—Quick-lime is used. We are not practically familiar with the manufacture, but presume them to be made by the manufacturers and dealers in philosophical apparatus.

OPAL.—There is no process of printing direct on opal glass without the intervention of a film. A surface must be sufficiently absorbent to receive the chemicals forming the sensitive coating. Possibly a process might be devised in which a sensitive coating could be formed on a ground-glass surface sufficiently adherent without a film; but we have never heard of any attempt of the kind. It would be troublesome, and possess no advantage that we can see.

CAPTAIN THETFORD.—The best known method of preparing sensitive albuminized paper for keeping is to excite on a neutral bath, and wash the free silver away, as described in various articles in our last volume and in our YEAR-BOOK. The paper may then be packed tight by rolling up, or other means, and put into a tin box, air-tight if possible. In this state it will keep for some time; before use, fume with ammonia.

W. W.—We do not advise the use of ground-glass except for windows where direct sunlight constantly finds access. It intercepts a large amount of light, easily gets soiled, and is not easily kept clean. Blinds for occasional use are much better. Delicacy and softness are not the result of too little light, but of plenty of light judiciously arranged, and of chemicals in harmonious condition with lighting. 2. You may use less chloride of calcium. It is probably chiefly due to this that a little half-tone is lost. Or, better, still keep the bath longer before use. It will bleach most whilst new. 3. Of course the greater the amount of chloride of silver present the longer the time of fixing. 4. Yes; the cheapest will be good enough for the purpose. 5. The nitrate of ammonia has probably been contaminated with chloride, and the precipitate chloride of silver. A bath of nitrate of silver and nitrate of ammonia is best decolorized by means of a solution of chloride of sodium. 6. Carbonate of silver is alkaline. 7. The pads should not be sensibly damp, although not "bone-dry."

INGENIO.—Will this correspondent kindly send us his address, as we have a communication awaiting him.

AN OLD SUBSCRIBER.—We have not seen the lamp in question; but the probability is that the hydro-carbon will give a more intense light than the camphorated sperm oil; but the latter is safer in use.

P. R. II.—We have never met with such a case, and can only suppose it to be due to some curious defect in the paper. For a paper salted with six grains of chloride of ammonium and three grains chloride of sodium we should recommend a bath of from forty-five to fifty grains of nitrate of silver. If you send a sample of the paper unexcited, we will try to ascertain the cause.

JOHN B. BEST.—Thanks. In our next.

MARS.—Place a screen with an oval aperture midway between the screen which receives the image and the lens. The aperture may have a serrated edge. The size of the aperture must be regulated by the position, size of the plate, &c., and may easily be ascertained by experiment. 2. The opal picture which has turned yellow was probably fixed in old or acid hypo. You do not state what process you are using, by which you wish to obtain black tones. Do you work by development or by collodio-chloride?

EOB.—The negative from which the print enclosed is taken appears to be a good one. Except so far as the element of time is concerned, single lenses give very good results in portraiture, but the images are not quite so sharp, and the exposure is inevitably longer. One advantage is, that, as a rule, the single lens gives more depth of definition than the portrait lens. We shall have pleasure in hearing details of your printing experiments. 2. We have no personal familiarity with chloroform. It was recently introduced by Professor Gamgee with high praise, but we have since heard that it had been over-praised. As it is stated to be harmless, a moderately weak solution may be tried without much risk.

C. B. RIVERSDALE.—We should prefer that which you indicate by No. 1. The term true focus should mean equivalent focus if applied to a compound lens, but has no especial meaning applied to a single lens, except, possibly, to indicate that there need be no uncertainty. The screw adjustment, we presume, refers to a quick screw in the mount for adjusting the position of the stop. The lectures are not generally published. There was nothing especially photographic in the bearing of the recent lecture. We shall give the question attention when it arrives.

H. II. II.—The additional glass marked in your diagram will doubtless be an improvement, but you should obtain some side-light if possible. We should place the sitter and background at the west, in such a position that the north top-light acts as a high side-light. Try the use of a white reflecting-screen.

R. TUDOR WILLIAMS.—Thanks. The prints are very excellent indeed. We will write to you shortly.

DAVID REES.—Thanks. We will communicate with you personally.

Several Correspondents in our next.

FORMULE IN AMERICAN STUDIOS.

A VERY natural curiosity generally prevails as to the precise formulæ used by the most successful photographers. It is true that it is almost invariably found that a knowledge of these formulæ, when gained, rarely reveals any great novelty, the materials used and the proportions in which they are employed differing little in the studios sending out the finest pictures from those used issuing the meanest travesties of which the art is capable. Still it is pleasant to know that ordinary chemicals, in ordinary proportions, have produced this exquisite gem or that picture of rare grandeur which has won the admiration of all beholders. The *Photographer's Friend*, an American quarterly journal, in recognition of this interest, gives details of the formulæ used in four of the most celebrated in New York, those of Kurtz, Gurney, Fredericks, and Napoleon Sarony, all of whom issue as fine work as can be desired. Mr. D. D. T. Davie, an old and well-known photographer, proposed a trial of skill to these four photographers, Mr. Davie himself sitting to each for the test negative. The result was in each case, we are informed, very excellent; but whilst the character of the result was different in each instance, the general excellence was so great that no decision could be made as to which was absolutely best. Details of the mode of producing each portrait were then furnished at length, the most important portions of which we reproduce. Before doing so, we call attention to a fact characteristic of American institutions, which will interest many of our readers. It is customary here, and more or less throughout the world, for the principal of an establishment to be recognized as the producer of all the work issued by it, the persons employed in the work sinking their identity in that of the establishment. We do not here discuss the propriety of this practice, as much can be said on both sides; we merely note it to point out the variation. In sending in the formulæ from each studio, it is done, in each case, under the name of the operator whose work is concerned, and the printer producing the prints.

FREDERICK'S FORMULÆ.

Dating from Frederick's studio, Mr. Hugh O'Neil sends the following:—

Cleaning the Glass.—Immerse the glass for several hours in a strong solution of common washing soda, then wash well under a tap, and stand them up to dry. Finish with alcohol and Joseph paper.

Negative Bath.—This bath should be kept 40 grains strong, iodized with iodide of silver, and made slightly acid with nitric acid.

Collodion.—Ether and alcohol, equal parts; iodide of ammonium, 4½ grains; bromide of potassium, 2 grains; gun-cotton, 6 to 7 grs., washed in ammonia; excite the ether and alcohol, then add the cotton.

Developer.—Water, 2 qts.; protosulphate of iron, 2 ozs.; acetic acid, as little as can be used, and have it flow well.

Re-developer.—Citric acid, 50 grs.; pyrogallic acid, 25 grs.; water, one pint; add a few drops of the bath silver solution just before using.

How to Renew the Bath.—If additional silver is required, add it to the bath, then boil down one-half, add as much water as is necessary to give the proper strength, then filter, and it is ready for use.

Fixing the Negative.—Nearly saturate water with hyposulphate of soda, to which add ½-oz. cyanide of potassium.

Mr. James Watson, the foreman printer of the same establishment, sends the following details of printing:—

Silver Solution for Sensitizing the Paper.—Solution, 35 grs. of silver to the oz.; to each ½ gall. of solution add a ¼ oz. muriatic acid. Neutralize with liquid ammonia. The muriatic acid forms chloride of silver, which filter out, continuing to use the same filter. Float 30 seconds, and fume 10 minutes.

Toning Bath.—To ½ gall. water add ¼ oz. saturated solution of common washing soda, or enough to make it feel slippery to the fingers, then add chloride of gold sufficient for the occasion.

Fixing Bath.—Water, ½ gall.; hyposulphite of soda, 12 ozs.

Remark.—By this method the strength of the picture is not very much reduced. In washing your prints, to the two first waters add acetic acid in proportion as one drachm to 2 qts. water; let the third washing be done in plain water, preparatory for toning.

GURNEY'S FORMULÆ.

Dating from Gurney's studio, Mr. James L. Forbes gives the following:—

Cleaning Glass.—Immerse the glass several hours in a strong solution of potash, or concentrated lye; then wash carefully under a tap, sponging the glass thoroughly; and finally rinse very carefully, and dry on nails in a room free from dust and stench. Before using, rub the side that is to receive the picture with a few drops of alcohol and Joseph paper.

Negative Silver Bath.—I keep my bath as near 40 grs. to the oz. as I can, slightly acidulated with nitric acid, and iodized with iodide of silver, and occasionally reduce it one-half or thereabout, and boil it down one-half or three-quarters, then reduce to proper strength, and filter. If fresh silver is required, add it before boiling.

Collodion.—Ether and alcohol, equal parts; iodide of ammonium, 5 grs. to the ounce; bromide of cadmium, 1½ grs.; and bromide of ammonium, 1¼ grs.; cotton, 5 to 7 grs. I find this collodion works best from 10 to 30 days old.

Developer.—Protosulphate of iron, dissolved in water, 25 grs. of iron to the oz. of water, and as little acetic acid as will make it flow evenly.

Remark.—I rarely redevelop, but occasionally find it necessary, and use the ordinary pyrogallie preparation.

The printing details at the same establishment are sent by Mr. John J. Street, as follows:—

Sensitizing Bath.—Water, 1 oz.; nitrate of silver, 40 grs.; ammonia, 1 drop, or slightly alkaline; float 40 seconds, and fume 10 minutes.

Toning Bath.—Water made alkaline with common washing soda; add chloride of gold enough to do the required toning. After the gold is in solution it should be sufficiently alkaline to change litmus paper readily. The tone of the picture will be varied by more or less exposure in the bath.

Fixing Bath.—Water, 1 gal.; hyposulphite of soda, 12 ozs.; common salt, 1 oz.; fix until the prints are thoroughly clear, and no longer. Before toning, wash the prints in at least three waters, using 4 drachms of acetic acid to the gallon of water for the two first washings, and finally wash in plain water.

(To be continued.)

PERMANGANATE OF SILVER FOR PURIFYING THE NEGATIVE BATH.

It is somewhat curious, at times, to note the progress of discovery and re-discovery. About four years ago we published, in these pages, the first suggestion of the use of permanganate of silver for the purpose of removing organic matter and other injurious substances from water for use in the silver bath, the article being from the able pen of Mr. Wm. Crookes, F.R.S. Taking advantage of the well known property of permanganates in oxidizing organic matter, Mr. Crookes undertook some experiments with permanganate of silver, and proved its complete efficacy. Putrid water, from a pond mixed with old hypo baths, cyanide solution, putrid albumen, and other deleterious substances, was found, after treatment with the proposed salt, to be perfectly pure and fit for use in making a nitrate bath. Twelve months later, Mr. J. R. Johnson read a paper at the Photographic Society, detailing experiments suggested by those of Mr. Crookes, in which permanganate of potash was used for removing organic matter from a fogging nitrate bath, and with complete success. The relative value of the plan of adding permanganate of silver direct to the bath, and of forming it in the bath, was at the time discussed in our pages, the general conclusion being in favour of permanganate of potash as an equally efficacious and more accessible salt. In a recent article in the *Photographische Zeitung* the value of permanganate of potash being admitted, the superiority of permanganate of silver is suggested, but without any reference to the original proposition. Our chief object in referring to the matter is not, however, to refer to this omission, but to point out the fact that, where permanganate of potash is used with reasonable care it does not, as is suggested, introduce anything which is calculated to injure the bath; and that permanganate of silver used without care may be found very injurious. Although it is very insoluble, it may remain in solution in the bath to the extent of four grains in each ounce, in which proportion, or less, it would be found a powerful retarder, materially destroying sensitiveness. If, after correcting a bath, any trace of colour be apparent, due to the presence of permanganate of silver in solution, the bath should be filtered through clean filtering-paper, the contact of which will decompose and remove the excess of permanganate.

THE VICTORIA CARD.

NOTWITHSTANDING the coldness—or, rather, we should say, perhaps, the indifference—with which the portrait *format* recently proposed by our American neighbours has been

received in this country, the chances of its ultimate success are becoming every day greater. It will be remembered that the suggestion to start a style of portraiture between the sizes of the carte and cabinet was in the first place made in the last September number of the *Philadelphia Photographer*, the dimensions proposed being five inches long by three inches and a-quarter wide, and the name of "Bon Ton Carte" was mentioned as an appropriate designation for such pictures.

The pretensions of the new size consist mainly in its convenient form and dimensions, which are stated to be those of an ordinary envelope; in its economical production, from the circumstance that albuminized paper may be cut up without waste; and in the fact that ordinary carte lenses and appliances are suitable for obtaining them. The proportions being larger than those of the carte, the size of the portrait when taken full-length is not so excessively small, while for the bust pictures, so prevalent just now, more margin could be allowed, and thus the finish and effect considerably improved. Of course, there are several objections that could be offered in one way or another against the introduction of a new style of picture before the cabinet form is more thoroughly established in this country; but, then, we must remember that England has certainly been more backward in adopting this latter form of portrait than other countries, and that while cabinets are still a rarity with us, with some foreign photographers they are as much in demand as cartes. But the cabinet is in any case always an expensive production, and when ordered by the dozen necessitate some considerable outlay on the part of the customer, and for this reason alone it can never become thoroughly vulgarized. At the same time we are all agreed upon the fact that the carte is, as a rule, too small to render full justice either to the photographer or his model, and that some extension of its limits would certainly be desirable if such innovation could be made wisely and with one accord.

Whether it is desired to adopt the new style in this country (for we have not, as yet, seen any English pictures of this description) is, however, not now the question, for, instead of being a matter of choice with us, it will, in all probability, be a matter of necessity. The "Bon Ton Carte," or Victoria Card, or Elizabeth Card, as it has been successively called, has already found sufficient favour and support in the eyes of foreign photographers to render it altogether independent of the behaviour of English artists. It was just the same in regard to the cabinet picture in this country; for some time after this elegant form had been proposed, there was no energy or enterprise exhibited by us to push the same forward, and to establish it on a firm and substantial footing, and it was not until half a dozen decided and resolute artists, such as Notman of Montreal, Rentlinger of Paris, Milster of Berlin, Angerer of Vienna, &c., took the matter up, that there was any chance of its adoption as a type by photographers, and then, as a matter of course, the form became universal, in spite of any individual opposition.

We believe it will be very much the same thing with the Victoria Card. The form is altogether a good one, and has much to recommend it, and accordingly, on its announcement in the various journals, it was received with unusual favour. Poor Paris has, of course, been unable to speak her mind in the matter, but at New York, Berlin, Vienna, and St. Petersburg, the new card has been promptly adopted, and this, not by firms of unknown repute, but by some of the best portraitists of the day. Thus, among others, we may mention Anthony of New York, Fritz Luckhardt of Vienna, and, we believe, Loescher and Petz of Berlin. M. Luckhardt, who, by the way, has just been appointed Imperial Photographer, introduced the pictures on a recent occasion to the Vienna Society, and loyally proposed to substitute the name of Elizabeth for that of Victoria, the former being the name of the Empress of Austria. He has already briskly commenced

the production of them at his Viennese studio, for they are, in fact, very suitable for those large bust pictures with which his name is associated. The *Mittheilungen*, *Correspondenz*, and *Archiv* have all given full and explicit directions in regard to the sizes and production of the cards, and have exerted themselves to give publicity to their claims and advantages, and there is no doubt, therefore, that the combined influence of the foreign journals and leading photographers will have the effect of rapidly bringing the Victoria Card before the public.

The manufacture of albums suitable for this particular form has, in all probability, not yet commenced, but should the public verdict be favourable, and should Paris photographers hereafter adopt the size, albums will soon be forthcoming, for the interest of the manufacturer is identical with that of the photographer in inducing or pushing the demand for new articles. During the coming season there would be a good opening for a novelty of this kind if properly placed before the public, and we fully believe that the style would become a popular one, which the cabinet picture, owing to its cost, can never be. Let those, of course, who find a ready market for large pictures, keep open that market; but where cartes-de-visite form the staple article of demand, the Victoria Card will be a real and welcome innovation.

PHOTOGRAPHY AND ITS RELATIONS WITH THE STATE.

BY STEPHEN THOMPSON.

OF all the applied sciences—and photography, in many of its aspects, is a piece of pure science—I here hazard the assertion that not one has been so little indebted to governmental aid in its development and progress as photography. Indeed, it owes literally nothing to State aid; which is more than can be said of contemporary sciences equally prominent—such as geology, astronomy, telegraphy, and others. And yet one constantly hears, at popular lectures and literary and scientific gatherings, photography and telegraphy spoken of as the two great inventions of the age! Neither has it made its way without, in some quarters, unfair criticism, and even injustice; and in others fierce obstructiveness, and obloquy. This, perhaps, was owing to the fact that, unlike telegraphy, which displaced no rival, interfered with no vested interests, photography, in some fields, *has* done so. However, photography had no helping hand, and thus may stand before the public with all the just pride, even bordering on arrogance, of the self-made man. Neither is it that it was immediately self-supporting to all who took it up. Mountains of gratuitous labour have been contributed to it in all directions. Geology and telegraphy were sooner converted into professional and payment-charging pursuits.

On the other hand, the State has not scrupled to appropriate, on various occasions, the results of the labours of the photographic community without acknowledgment. On one notable occasion it did so, and rewarded the mere organizer of a governmental department with a knighthood (!) When one remembers the labours of Poitevin and others who bore all the heat and burthen of the day, one is apt to wonder at the disposition of all mundane things, and to ejaculate such fatalism as is implied in the Mussulman's apostrophe, "Great is Allah, and Mahomet is his prophet!"

The Government at all times arrogates to itself the right to use any patent whatever in the service of the State, without reference to the patentee, and, by some pleasant fiction, is supposed to compensate the patentee in exact proportion to the use made of his invention. But, through inexperience or bungling, great damage may be done to the *prestige* of an invention, of which the patentee becomes the sufferer.

The American eclipse expedition of a year or more

ago—admirably planned, admirably carried out—might have shamed the powers that be, when another occasion arose, into the recognition of the existence of the *Photographic Society*, a body properly organized on the same basis as other scientific societies, taking cognizance of all matters appertaining to the specific sciences for which they were called into existence. When the £3,000 so tardily awarded for the purposes of the expedition was distributed, although photography was confessedly of the utmost importance in connection with it, calling for the very best aid, and the best appliances that could be obtained, the members of the other scientific societies were allowed to expend the whole of the money without one thought of their younger sister in science. When her existence and importance were at length suddenly remembered, it was not considered at all immodest to expect her to find all her outfit, *matériel*, &c., for the campaign, at her own cost. Is this fair? Is this kind of thing to go on? Why is photography, as represented by its Society, not to be consulted, and have communications opened up with it like others? Quite recently the Ethnological Society, in the person of its president (Prof. Huxley) and council, was consulted by the Government on a much less important matter. Would there be anything *infra dig.* in communicating with a president of Mr. Glaisher's scientific standing, and the council representing the Society? Is photography always to do yeoman's service?

En passant, with customary wasteful economy in such cases, the tardy grant necessitated such hot haste that it may be fairly questioned whether it did not indirectly lead to the loss of the "Psyche," with one section of the breathless party on board. The whole thing was hurried. The dispatch, in midwinter, of the "Psyche" from Naples to Sicily well illustrated the Laureate's line—

"Raw Haste, half-sister to delay."

Ten minutes hurriedly begged of the commander from the deck by Mr. Norman Lockyer for consultation below, and in half that brief time the young sub-officer in charge had lost the ship. Counting the value of H.M.S. "Psyche," the cost of futile efforts to get her off the rocks, court-martial, and other contingent expenses, probably in all some £50,000—enough to pay for all the eclipse expeditions for the next half century at least.

A fitting time has again arrived to re-open this question, because the State will shortly need to avail itself of the latest and most perfect developments of photography as a science. This is to be a military session, as everyone knows. With the general questions of army efficiency the daily press will deal. The specific one of photography in its applications to war purposes our own journals may fairly discuss. At the head of the department of military photography at Chatham there is now an officer of proved ability and rare zeal. There should be no cheese-paring policy pursued in its administration. Lt. De W. Abney, R.E., should have placed at his disposal ample means to put it on an even better footing than that of the Prussian service. The Society should not be ignored when occasion offered. Two heads are better than one in such matters. Many valuable hints might be given in details of organization. We know the enormous use made of photography by the Prussian army. But years before the war broke out the same forethought was exercised in photography as in other branches of the service. It is known that Prussian officers "settled down," before the campaign in Austria in '66, as "photographers" in villages and small towns situate in districts where topographical knowledge was likely to be "wanted," pursuing their business as if for a living, taking cheap portraits, and, while ostensibly taking local views about, secured all the topographical and strategical features of the country, and then disappeared. When next seen in those localities, it was in uniform at the head of their men. This was also done in France. I do not say we should exactly follow their example, but I do say that we should possess a bureau

for the deposition of topographical knowledge of places it is known that in the event of war we should require some knowledge of.

To organize a thoroughly efficient and reliable military department of photography is an object worthy of the ambition of any man. It might be made a storehouse of information, an unerring and indisputable historical record of facts, a circulating channel of important information, and, by microscopic reduction, a means of communication when all else fails, a topographical *compagnon de voyage* that never misleads, and a general *aide de camp* indispensable in modern warfare. Photography is a science as well as an art, and possibly might, in competent and daring hands, be made of as much importance to an army in the field as telegraphy. As well as an efficient staff at quarters for the rapid multiplication of proofs, photography should have its Uhlans. In *reconnaissance* it might be made most useful. With well-devised and extremely portable apparatus and a sensitive dry-plate, and the exercise of tact and intelligence, information might frequently be obtained of more reliable value than verbal reports. The matter is an important one. It is not sufficient to do what has already been done by others in this direction. *Not to advance is to retrograde* in such matters.

One of the most remarkable features of this war has been the extraordinary topographical knowledge of an enemy's country displayed by the Prussians. Only the other day, in a remote district on the Loire, a great success was attained, while a battle was raging, by a minute knowledge of the ground furnished by the Prussian system. Modern warfare is more a game of skill than ever it was, and that power is best prepared which most ably avails itself of the appliances modern science has placed at its disposal.

The French error of excessive organization should be avoided. When the strain comes, a single establishment is not always equal to it. Should, by the very ordinary contingency of illness or wounds, the chief, or chiefs, be placed *hors de combat*, the whole department would be liable to break down at once.

In addition to the establishment at head-quarters, there should be branch establishments localized at all important commands, such as Aldershot, Shorncliffe, Portsmouth, the Curragh, &c., and they would furnish the additional advantages of familiarizing the army to its uses and operations, and give the staff the necessary rehearsals of their duties in mimic warfare. The Prussian forces were continually exercised in all the minutest details of an army on the march, and taught how to deal with all possible contingencies and difficulties of real warfare.

The organization of a complete system of military photography is of the first importance. And here, at the very outset, arises a source of danger which it is most essential to guard against.

There is a disposition abroad just now to rely too much upon organization. That it is "German organization" that has achieved all the recent successes is the belief of many. The question presents itself, what is organization? In itself, organization simply means the provision and arrangement of organs with a view to the performance of different functions in a co-operative manner; and organization may easily be made so elaborate and complicated as to defeat the very objects for which it was contrived. System is of use only so far as it can aid or replace individual energy and intelligence. Without some kind of organization there could, of course, be no cohesion or concentration of effort. On the other hand, room must always be allowed for individual discretion and intelligence. The happy medium lies between too much and too little organization—a system sufficiently compact and sufficiently elastic to admit of a good deal of personal freedom of action. The more the German organization in all its branches is examined, the more it will be found to owe its success quite as much to its freedom and elasticity as to elaborate preparations

beforehand. It is hard to say whether there is more danger in trusting everything to the inspiration of the moment, with a blind confidence that, somehow or other, one will pull through, or in relying on rigid pre-arrangements, which may not only be useless, but mischievously destructive, in the event of things not turning out exactly as expected. The secret of German success I believe to lie in the superior intelligence of all placed in the smallest offices of trust, the division of labour among them, the great discretion then safely allowed, and the responsibility thus directly fastened upon them.

This brings me to an important part of the subject. Photography is a pursuit that requires for its successful practice habits of forethought, and reflection, and exactitude, and a far higher intelligence than is commonly supposed by the outside world. These qualities are requisite for its ordinary practice, while a yet higher intelligence, that of the man of science, may find it *a sea to swim in*, and not the mere puddle popularly imagined.

It will be quite inadequate for the chief of the staff to be *facile princeps*, unless a high standard prevails amongst all his subordinates. Ubiquity is impossible; and when disappointments and break-downs come, as come they may, theirs may be the fault, and his the ignominy. It takes years of training ere men can be thoroughly up to getting good photographs with a field equipment *under every possible variety of circumstances*. In my own experience, extending from the Hebrides to the Alps and the Apennines, I know how many capable men I have found who are always at fault and resourceless away from the appointments of a laboratory. Men like Mr. Bedford, Mr. England, and others, must have much to suggest as to field equipment, and its essential requisites for specific purposes away from a base of operations. One must grow accustomed to such small accidents as a tent blown over on a bleak mountain side in a sudden *sirocco*, and the improvising temporary shifts and expedients, to say nothing of graver matters.

The essentials, then, are organization up to a certain point, remembering that it is a thing of which it is possible to have too much, and a superior class of well-paid subordinates (the cheapest ultimately), who can be trusted to sometimes think for themselves. It is very easy to make so many organized arrangements beforehand—swathing oneself, so to speak, in so tremendous an equipment, and overloading oneself with so many implements and accoutrements—as to be unable to stir a step. There were many vulnerable points in the Abyssinian Photographic Department, which would have infallibly broken down had it been subjected to the strain of being harassed by an enemy in an enemy's country, as might have been reasonably expected.

I will conclude with an amusing instance of the prevailing tendency to attribute everything to German organization, and nothing to personal or more mobile qualities, related in a leading journal a few days ago. An Englishman who had been dining at the head-quarters of the Prince of Saxony had just reached the door of his lodgings, when a provision waggon which was passing suddenly broke down. It was discovered that one of the wheels had given way; and our countryman was still wondering how the deficiency could be repaired, when the driver quickly produced another wheel in a stolid, matter-of-fact way, as if he had anticipated the accident, and had taken care to provide himself with an ample supply of extra wheels to meet every contingency. The new wheel was put on, and the waggon rolled on as if nothing had happened. It must be confessed that a more striking example of the providence and promptitude of German organization could hardly be desired. Far away from a wheelwright, on a lonely country road, in the middle of the night, a wheel breaks; and yet so thorough is the organization that, in a few minutes, another wheel is on, and the waggon once

more rolling onwards. Admiringly pondering these things, the Englishman happened to glance at his trap under a shed, and observed something peculiar in its appearance. The wheel of the trap was gone! It was this wheel, in fact, which he had just seen stuck on to the provision waggon. The incident gave his thoughts a new turn in regard to the much-vaunted system. I leave its application to the subject under consideration to others.

THE SOLAR ECLIPSE IN SICILY.

BY DR. H. VOGEL.*

SINCE the occasion of the great eclipse in 1868, which I had the opportunity of observing as a member of the North German expedition, our scientific knowledge of the sun has much increased, the new method of observation by means of the spectroscope having yielded some very surprising results. The puzzling nature of those cloud-like flames which extend for many thousand miles around the sun are now capable of being examined at other times besides that of an eclipse; and, indeed, the only point upon which information was still anxiously sought for was in regard to the corona, that bright halo of light which, on the occasion of totality, is seen to envelop the protuberances and limb of the sun. The excellent observations made by the Americans in August 1869 yielded some interesting results in regard to this "crown of glory." Its wonderful trapezoid form, for instance, was secured photographically; its nature was tested by means of the spectroscope and polariscope, and the data thus obtained seemed to establish the fact of its being a description of aurora borealis surrounding the orb.

The scientific results were, however, by no means conclusive on this point, being, in some cases, of a contradictory nature, and many philosophers expressed an opinion as to the phenomenon being due simply to our own earth atmosphere; and it was mainly for the purpose of setting this point at rest that a resolve was made to prosecute the research on the occasion of the solar eclipse of the 22nd December, which took place in Southern Spain, Algiers, Sicily, and Greece. The Americans were the first to seize this valuable opportunity for further experiment, and fitted out for the occasion two expeditions furnished with means of a most efficient nature, one of which was despatched to Spain and the other to Sicily. Their example fired the enthusiasm of English and Italian astronomers, as also that of the Austrians, MM. Weiss and Oppolzer being sent out to represent the interests of the latter, and it was only, indeed, the Germans and the French who remained behind. *Inter arma silent leges et scientiæ.*

An invitation had been extended to me to join the English expedition, one which I gladly accepted, notwithstanding the circumstances that I had but just returned from my long and pleasant American journey, and had not yet quite settled down in Europe; and despite, moreover, several inconveniences in regard to time and means. To travel through Germany, in mid-winter, as far as Trent, in the Tyrol, when the ground is hidden by a thick coverlet of snow, and the thermometer marks eight degrees of frost, and the railway arrangements are out of order by reason of the war, is by no means a pleasurable undertaking. The glory of beholding the scenery of the Bavarian Alps and Inn Valley is, moreover, considerably lessened by the physical sensation of freezing, and even Munich, in such weather, notwithstanding a bright December sun, created a most frosty impression. It was at Munich that I joined the English expedition bound for Sicily, another staff having been despatched to Cadiz, and a third to Oran. The Sicilian expedition, including your humble servant, consisted of seventeen members and two assistants, under the direction of Mr. Lockyer, the well-known spectra analyst. Duties had been already assigned to the various members of the staff, seven being detailed for spectro-

scopic observation—among whom were Mr. Lockyer and a lady assistant, his wife, as also Professor Roscoe; four were told off to polariscope observations, two were to sketch the corona, and three—Mr. Brothers, Mr. Fry, and myself—were to be engaged in photography. Moreover, Mr. Thorpe was to occupy himself with photo-chemical measurements, and Mr. Viguolle and his son with time and general observations.

This short sketch of our programme will show that every possible exertion was made to scrape an acquaintance with the corona, and to lift the veil which hid its nature from us. Truly, it could not have been assailed with more vigour and energy had it been an earthly crown.

The expedition was equipped in a most excellent manner. A courier speaking fluently the English, French, German, and Italian languages, occupied himself with all business arrangements, and provided the necessary railway tickets, quarters, refreshments, carriages, &c., the personal comfort of the staff being greatly enhanced by their occupation of one saloon compartment during the whole of the journey from Cologne to Verona. Fortunately, the speed of the journey was now and then slackened, from a desire to afford our lady companion some interval of rest; and thus, at Verona, half a day was allowed, which was spent, for the most part, in visiting the lions of the city. The more quickly, however, had we to speed through Vicenza, Padua, Ferrara, Bologna, and Florence; in Padua, indeed, I was the only one who, during the one hour's halt, was successful in making a visit to the Cathedral of St. Antony. At Verona we arrived on the 10th December, where we found a comparatively mild temperature; but farther south snow lay upon the ground, and we were colder actually than we had been in Germany. It was only when we reached Tuscany that we found ourselves in a warm climate, and that the myrtle and laurel showed us that we really were in Italy. But it was truly pitiable to be compelled to rush so swiftly past all these beautiful places, and to turn over, at a time, sixty or eighty pages of the guide-book in our hands, telling us of glorious things and places well worthy of inspection.

In Rome we were allowed one day of repose. Who could rest, however, in the midst of such wonders of all ages as are here gathered together? Regardless of all pain and fatigue, we rushed out from the Hotel Constance to visit the Piazza del Popolo, the Corso, the Engelsburg, St. Peter's, Montorio, Via Appia, St. Paul's Basilica, the Catacombs, and came actually before sunset to the Therma of Caracalla, the Colosseum, the Forum, and the Capitol. It was, in truth, a giant's tour; but the beauty, novelty, and grandeur of the scenes exerted quite an electric influence upon one's nerves, and it was not until our return to the hotel that any feeling of fatigue was perceptible.

A twelve hours' railway journey brought us to Naples. The weather here was, unfortunately, very unfavourable, the cloudy sky allowing one to appreciate but few only of the beauties of this earthly paradise; but even if this had not been the case, the arrangements for the prolongation of our journey would have prevented us from enjoying any opportunity to visit the neighbourhood.

(To be continued.)

NOTES ON THE COLLODIO-BROMIDE PROCESS.

BY HENRY COOPER, JUN.*

THE best way of utilizing the residue remaining after preparing a batch of plates, is to mix it with a quantity of plain bromized collodion, say six fluid drachms, and place it in a clean bottle. The residue of the next batch may be likewise added to it; and when sufficient has thus accumulated, it may be fully sensitized and used up. As the resensitizing will have been done only once, the plates prepared with it will not differ greatly from those pre-

* *Photographische Mittheilungen*

* Continued from p. 43.

viously made. The residues must not on any account be mixed with the stock emulsion.

You will doubtless have noticed that I recommend that the solution of nitrate of silver in alcohol should be allowed to cool before pouring it into the bromized collodion. This is certainly the best way when using a pyroxyline thoroughly adapted for this process; but if we have to work with a rather horny and new collodion, we can take advantage of the physical effect of heat upon the pyroxyline, and add the alcohol whilst it is nearly boiling. (Need I say that in such a case the bottle containing the collodion must not be allowed to stand near a flame when the temperature is thus raised?) I remember on one occasion having a rather large quantity of collodion that I could not use at all, when employing the tube-mortar method, for the bromide was invariably thrown down in stringy-looking lumps. I then tried adding the silver in solution *cold*. The bromide was no longer precipitated, but the film given was most unsatisfactory. As a last resource, I added the silver and alcohol whilst boiling hot, and to my great delight I obtained some most excellent plates with the previously unmanageable collodion.

I will not detain you with the details of the preparation of the plates, as they have been so often fully described, though I must touch slightly on one or two points.

A substratum of some kind is necessary with most collodions; I prefer 1 gr. of pure india-rubber dissolved in 1 fl. oz. of chloroform. One thing I have learned by experience is, not to make up much of this solution at a time. I have so often noticed that when freshly mixed, the collodion will take kindly to, and flow easily over, the slight film of rubber upon the plate; but, after a time, the same solution will give a film that energetically repels the collodion in a most tiresome fashion. By mixing with some newly made solution this annoyance will cease for a time. Had there been time, I should have liked to have called your attention to some other curious freaks of the rubber solution, but must forbear.

After the collodio-bromide has well set, the plate is washed in two changes of filtered water, and then soaked for an hour in a pan, or other convenient vessel, holding a good bulk of water. With less soaking, the plates will not be so sensitive. I am aware that by so arranging our collodion as only to leave a *minimum* of free bromide, we could dispense with this washing altogether; but, on the whole, I think it safer to adopt the proportions of nitrate of silver and bromides recommended. In working with small quantities of material, it would be exceedingly difficult to avoid error if the proportions were too delicately balanced.

I have tried many preservatives for these plates, and of all that have come under my notice I prefer a mixture of gum arabic, tannin, and sugar. For ordinary use, the following proportions have been found to work exceedingly well:—

Gum arabic	15	grs.
Tannin	4	"
White sugar	4	"
Distilled water	1	oz.

This must be used the same day as mixed, and may be poured over the plate and retained on the surface for about a minute in the usual way. Unless a large number of plates are in progress, it is better to apply the organifier in this way than by immersion of the plate, as sometimes recommended.

The plates must be backed to prevent blurring. The exposure ought to be about twice that required for a good wet plate, though sometimes I have found collodio-bromide very nearly as sensitive as the wet.

The details of alkaline development are so well known that I need not go into this part of the process here; but there is one point to which I desire to call special attention: that is, that plates prepared as I have described will usually require an intensification with acid pyro and silver.

We have, hitherto, been generally led to expect that no silver would be required in the development, and that the full intensity could be readily obtained with pyro and ammonia alone; and I have met several persons who have been greatly disappointed at finding they could not thus satisfactorily develop their plates. Collodio-bromide plates can very often be brought up to the full intensity with the alkaline developer alone; but although these plates are very beautiful to the eye, they are not nearly so good as *negatives*—as those that have required and received an intensification with silver. Experimenters are sometimes apt to forget that the great end of any process is to produce *good pictures*; and that, therefore, the negative is only one of the means, although undoubtedly the most important, for obtaining this end. Our best workers will, I am sure, fully bear me out when I say that, as a rule, the prettiest negatives do not give the best prints.

A freshly mixed emulsion of collodio-bromide, or one containing a large proportion of soluble bromide, will often give plates requiring no intensification; but when the collodion has been got, by keeping or otherwise, into such a condition that the plates prepared with it shall be very sensitive, and at the same time give, with proper treatment, a really good printing negative, it will generally be found that the image produced by the primary development is exceedingly thin and delicate, and if we attempt to force the intensity with the alkaline solution, fog will probably be induced. As soon as the details are well out the plate should be thoroughly washed, flooded with acid pyro, and then intensified in the usual way.

The colour of the image varies so much (often from bright orange to pale green or brown) that it is a good plan to sometimes print a trial proof before varnishing.

If found too weak, it may easily be strengthened with more silver and pyro, preceded by a wash of iodine solution, or with uranium and red prussiate of potash.

By far the safest and best mode of using this latter intensifier is to wet the plate, and then flood it with a sufficient quantity of a five-grain solution of nitrate of uranium; after allowing it to soak into the film, pour off the solution into the measure, and mix it with an equal quantity of a five-grain solution of red prussiate of potash; return the mixed solution to the plate, and keep it in motion until the desired effect is obtained. If any great amount of intensification is needed, it is better to first strengthen the image with silver and pyro, and then change the colour with the uranium. Although by continuing the application of uranium and potash almost any depth of tint may be obtained, yet it is not wise to force the effect of this intensifier, as I have often found the film split up on drying when the intensity has been thus pushed. The colour materially darkens on drying, but upon varnishing the plate it returns to the same tint as when wet.

If, on the other hand, the negative be too intense, it may be reduced by soaking for a few minutes in a solution of iodine and iodide of potassium (half gr. of each to one oz. of water), and then transferring the plate to a *very weak* solution of cyanide. The same method will very often answer for removing a slight veil of fog, whether caused by over-exposure or abnormal reduction. Of course, great care is needed in using the iodine and cyanide; but if they are sufficiently dilute, it will not be found difficult to control their action upon the image.

This paper has so much exceeded the limit I originally intended that I have not space to enter upon the interesting question of the effect of a *chloride* in the collodion. I must, therefore, defer until another opportunity the remarks I had wished to make upon this branch of the subject.

Many friends, among them Mr. Spiller, are well aware that this point has engaged my attention for *more than two years*, and I hope, at some future time, not only to publish the results of my experiments, but to still further carry out my investigations.

In conclusion, I would add, that if I can assist any fellow-worker by further reference to my "Note-Book," I shall have great pleasure in placing at his disposal any records that I possess of other experiments.

USE OF PYROGALLIC ACID IN RECOVERING WASTE GOLD SOLUTIONS.

BY WILLIAM BELL.*

MANY photographers do not recover their gold from their waste solutions themselves, deeming it troublesome. Now no operation in photography is more simple or less conducive of trouble, and the slight trouble so well repaid. My mode is, to collect the used gold solution into a gallon bottle, and, when nearly full, neutralize the alcohol in it by hydrochloric acid, making it just acid (no more); then taking two ounces of pyrogallie acid solution to twenty grains strong; pouring this into the neutralized waste gold solution, shaking well; let it stand for twenty-four hours, to allow the precipitated gold to settle; then pouring off (into waste barrel) the upper solution, being careful not to lose any of the precipitate, which catch on a filter; wash two or three times in water. Now place precipitate and filter into an evaporator, and dissolve with nitro-muriatic acid (one ounce nitric to four ounces of muriatic); this I keep already mixed, using only so much at a time as is necessary to dissolve the gold; evaporate over a water or sand bath, and there is no danger of overheating in evaporating. The gold solution produced by precipitating with pyro will be found to be of the best toning properties—even better than that precipitated by iron, as there is always more or less danger of iron being present.

Correspondence.

CARBON V. SILVER PRINTING.

SIR,—There is one point in your carbon controversy with Mr. Bovey that I think you have overlooked, but which shows pretty clearly that he is practically ignorant of the process. I mean the plea that it cannot dodge or humour the prints as, by means of masks, double printing, &c., silver printing does: the fact being, that by means of hot water, a portion of a carbon print can be reduced to any extent during development; and, when mounted, you can again work on them to almost any extent with a sharp penknife.

The real fact of the matter is, that negatives at present are positively spoiled, by intensification, to fit them for silver printing, and are thus unfit for Swan's process, which gives the best result with delicate negatives that would not produce satisfactory silver prints.

Trusting that this may be of use, and that you will excuse such a hurried scrawl—Yours truly, J. COOPER.

Bowling Green Street, Leicester, January 26th, 1871.

CARBON, HELIOTYPE, AND SILVER PRINTING.

ICILIIUS—I would have pledged my life—

VIRGINIUS.—'Twas a high gage, and men have staked a higher
On grounds as poor as yours.

SHERIDAN KNOWLES.

SIR,—Mr. Bovey, it seems, is willing to stake his existence that if he were set up in heliotype printing, he would produce by that process results equal to anything, not only which carbon printing has produced, but to anything which it is "capable of producing under the most favourable conditions." When one reads a sentence like that, one is sorely puzzled to determine whether the writer holds his existence as a very worthless thing, or has not seen good carbon prints, or has a very imperfect appreciation of what good results are, or is simply indulging in an ebullition of that sheer nonsense he is so fond of denouncing in others. These and

similar alternatives pass through my mind; but I never dream for a moment—nor will any one else, I imagine—of believing that he can produce heliotypic results comparable to the best carbon has already produced. I will say nothing of what it is capable, for, as you have already shown Mr. Bovey, hypothetical arguments in such matters are worse than idle.

I will give my reasons for attaching no weight to Mr. Bovey's opinion, or pledge, as expressed. The heliotype process is, in its mode of working, strictly analogous to lithography, and its highest results must of necessity partake of the character of lithographic work. It cannot rise higher than the best lithography, and this, as every one in the slightest degree familiar with the graphic arts knows full well, is, at best, inferior to good engraving of any kind. The blacks have not, and cannot have, the same depth and richness possessed by the engraving, and, as a rule, a weak woolliness prevails. Carbon prints, on the other hand, have been issued, which have been, and are, accepted as fine engravings. So much for the possibilities of heliotype printing; as for what it has already effected, still less can be said. Take the examples at the last exhibition in Conduit Street. Carbon was very imperfectly represented there, whilst the heliotype process was exceedingly well represented; but did the results admit of the slightest comparison? Was the best heliotype print equal, in any one point of excellence, to the noble print of the Manchester Cotton Famine Committee, sent by Mr. Sarony? Portraiture is said to be the crucial test of a process. Well, could anything have been finer than the carbon portrait exhibited by Messrs. Downey, or need anything have been worse than the heliotype portraits exhibited? The heliotype prints of rustic or architectural subjects, and reproductions, were better; but they, the latter especially, were rotten in gradation, showing all the special faults of the lithographic impression.

I do not wish to be unjust, and must, therefore, interpolate here my high relative opinion of the heliotype process. It is a high success of *its class*, and I hope for it wide success; but its class is of necessity lower, at its best, than carbon printing.

Mr. Bovey concludes his first article by saying:—"Make such results [silver prints] permanent, and the process cannot sink into oblivion until the day when the Heliotype or Woodburytype work shall be in a position to challenge comparison with the best silver printing." Make silver prints permanent! Is Mr. Bovey laughing at photographers, or is he aiming to make himself a laughing stock? Why, that is what photographers have been trying to do for a quarter of a century, and are now no nearer than ever. Mr. Bovey admits that silver prints are a "bye-word and a shame," and the exercise of a very little intelligence might convince anyone that if the possibility of change constitute a bye-word and a shame, that stigma must for ever attach to silver prints, because it belongs absolutely to the material of which they are formed. Ask any silversmith if he can keep his goods from tarnishing; ask any housekeeper if she can keep her silver teapot or cruet-stand from discolouration. The mournful negative will follow both questions. Until all silver is eliminated from silver prints, or until it is protected absolutely from contact with the air of towns, silver prints will be liable to change.

Another strange absurdity: Mr. Bovey denounces carbon prints as imperfect, and lauds Woodbury prints, when the fact is, they are in character absolutely identical. Both are prints formed of colour imprisoned in gelatine; but one is produced by light, the other by mechanical means. This is the advantage of the Woodbury process, that it may rival carbon, which any photo-lithographic process never can.

From Mr. Bovey's remarks about the limited capacity of carbon printing, and the impossibility of dodging, one is inevitably led to the conclusion that he knows nothing of it practically. The capacity of carbon printing, and its range of modifying power, is of necessity much wider than silver printing can possess. By modifying the proportion

* *The Photographer's Friend.*

of colour and gelatine, any kind of result, delicate or brilliant can be secured; by modifying the heat of the water, and prolonging or shortening its action, almost any degree of depth can be secured in developing, and this can be done locally, or generally, at will.

It is not difficult to understand why photographers generally delay, and hesitate to give up, their usual practice, to adopt something which may turn out difficult—may turn out a failure. They wait, naturally, for a few persons of position, reputation, and wealth, to set the example. It is the way of the world. And as no one has really a duty of this kind, each of the authorities waits his own good time, seeing no reason for risking anything until he is well satisfied, or has time, or can well afford the experiment. But I must confess that I think it unworthy of any photographer of respectable position to endeavour to justify a natural hesitation to change by an attempt to denounce or undermine the beautiful permanent process whose existence as an unadopted possibility is a shame and reproach to the whole of us as a body.—Yours truly,
X. Y. Z.

CARBON PRINTING V. SILVER PRINTING.

DEAR SIR,—As in war, so in logic, the defence of a weak position demands, as a rule, an exercise of subtle strategy which, in practice, is rarely complete in conception, more seldom still in execution. Now, in reference to the general tenor of your replies to the observations contained in my letter, whilst I tender my full admiration of your faithfulness, and of the skill evidenced in the construction of your defensive arguments, yet, as I read them, they convey to my mind an impression that you have unconsciously admitted the correctness of the chief points I urged against carbon printing, as you unreservedly admit, in reference thereto, that the present position of the process is not one of perfection. But you qualify the concession by the addition that the imperfections of the system are not inherent, but they arise from the limited extent to which the process has been hitherto worked; thus implying that a more extended band of workers are needed for the development of a complete success. Now, sir, before I proceed further, to be comprehensive, I restate our position in a few words.

I insist on the present imperfections of the carbon process, as compared with silver, for general work. You admit present defects, but imperatively insist on the certainty of its future development; thus it is made most clear that your reliance is based not on proofs realized, but on the assumption of what the future might unfold. But are you quite consistent in the line of argument you have chosen? By your own showing, if general evidence be inadmissible because of its inconclusiveness, still less can hypothetical evidence be admitted as sound argument; clearly this rule, if correct, should apply aptly to *pro* as well as *con*. Plainly you base the strength of your position, *not* on what has been accomplished, but on improvements which time has yet to unfold. This, to all intents and purposes, constitutes an argument based on that species of hypothetical evidence which you have unreservedly pronounced inadmissible.

[Our correspondent clearly misconceives our position. We readily admitted that as carbon printing is still undergoing improvement, it cannot be called a perfected process, and we expressed a conviction that increased experience would bring higher excellence; but we based no argument on this anticipation. We simply pointed out that no fair comparison could be made between the results of a process which had been practised by thousands of persons during thirty years, and those of a process which had been practised by tens only during six years; but, so far from basing an argument on hypothetical possibilities, we distinctly stated our conviction that, "in the balance of qualities, it is more perfect than silver printing now." It must be distinctly understood, however, that in commenting on Mr. Bovey's remarks, we have not entered in any complete manner upon a defence of carbon printing, but have rather

aimed to correct erroneous conclusions based on fallacious evidence. The major proposition of Mr. Bovey's lengthened argument was, that carbon printing had been tried and failed, and the minor proposition, that it had failed because of inherent imperfection; and the conclusion was, that it would never supersede silver printing. We denied both proposition and conclusion; but it was only necessary to point out that the alleged trial had not been made, and all the rest of necessity falls to the ground.—Ed.]

If, however, we take as granted that the carbon process is capable of greater extension, and requires only the fostering of a more general practice to develop its latent capabilities, the query suggests itself: can the supposition be brought within the bounds of reasonable expectancy that a patented process will ever receive the amount of attention silver printing has been and still is favoured with? This last system being free to all comers, improvements may be adopted by all without let or hindrance. But how stands this matter with protected autotype? Every experimentalist would, per force, be saddled with the depressing condition of paying for the liberty of working the process his labours to improve.

[This is an error; no charge is made for permission to work the process.—Ed.]

More than this, he would stand in danger of seeing his improvements snapped up by the patentees. He might succeed in improving the gelatine tissue (which is no difficult feat to accomplish), but he is forbidden to manufacture or sell such tissue without a license. Your reply to this would be: such improvement might probably be patented.

[An improvement may be patented or not, as the maker of it may choose; but he is quite at liberty to use it without patenting.—Ed.]

Hard to say; for in all my experience I have not known a patent so elastic in its specified demands as that filed in the English Patent Office by Mr. Swan.

[An elastic patent is useless; it must be specific. Eminent patent authorities say this is so.—Ed.]

Depend upon it, if the perfecting of a patented invention depends on the exertions of licensees, such invention will receive scant support, and few experimenting supporters.

[Herein we fully agree with our correspondent; the progress of a patented invention towards its highest development of excellence of a patented improvement is much slower than that of a free one. This is another of the unequal conditions of a competition in universality between carbon and silver.—Ed.]

This is certainly arguing on presumptive evidence; but in this respect we are, as I have shown, standing on equal ground.

In reply to your objection to the mention I made of names, I must direct your attention to the fact of the gentlemen named having, by their skilful works, raised the status of photography to a sphere of refinement, and an elevated reorganization, and that they certainly have strong claims to be regarded as the legitimate representatives of the art. It might, therefore, without cause of offence, be assumed that they, at least, would spare no pains to impart to their productions a permanent existence if it could be shown that quality is not compromised by the conditions of a yet untested means of stability.

[Until they have stated their reasons *pro* and *con*, no possible argument on the subject can be coupled with their names. It is true that the photographic community owe them something; but what do they owe the community, that they are to be placed upon their defence, or called upon for explanations, much less have arguments put into their mouths, until they desire to speak?—Ed.]

Doubtless the dodges as practised in silver printing might be successfully adopted by printers in carbon, in some instances. Nevertheless, dodging is sometimes practised on even the highest class pictures, which no blind mechanical means could execute.

A word about puffing. If my definition be correct, I

understand puffing to imply the over-rating of quality or qualifications. If, therefore, either of these are over-stated, the puff is as great a reality as a show advertisement which dubs Mr. Snooks "The Flying Horseman of the Prairie," or humble Miss Jincks "The Ariel Sprite" who licks creation at long jumps; no matter whether the representation proceed from a loudly worded advertisement or a soberly stated circular.

[Our correspondent overlooks the fact that he *assumes* this over-stating. We deny it.—Ed.]

You state your belief that in the balance of qualities carbon printing, even now, surpasses silver. This mode of generalizing is no reply to my arguments; but I will suggest a practical mode of answering them conclusively. Bring exceptional and experienced skill to the front—Mr. Johnson, for example. I have several hundreds of negatives which fairly average the products of photography. Let a skilled hand at carbon work take, haphazard, from among these, half-a-dozen plates, and produce from each a copy in carbon. I will follow suite with silver. If the carbon proofs excel, or even equal, the silver prints, "dodges" inclusive, I shall directly recall all I have advanced against the process, and henceforth will array myself on the side of its most ardent advocates.

[We shall have pleasure in seeing such a trial under fair conditions, and our correspondent will see that in another column Mr. Johnson proposes a similar test.—Ed.]

I ask such a test, because carbon workers have proved so singularly oblivious to the advantages for comparative trial offered by the annual exhibitions. In reproductions of drawings and line subjects (strong points of the process which I have always admitted), carbon printing has always been profusely represented, but in portraiture and landscape the examples have hitherto been few and far between.

[In our experience we have seen as many portraits as anything else in carbon. Portrait subjects have repeatedly been issued in carbon as presentation prints to societies, and always equalling silver.—Ed.]

You will probably feel disposed to assign, as a reason for the omission, that in reproductions of the kind stated, the process is chiefly employed; but this fact affords no proof of incapacity in portraiture.

[A very easy answer to this would be the simple statement that paintings, as a rule, being better art than photographs from nature, the printing process best suited to the highest art must have the best qualities. But the truth is this: reproduction has been undertaken as a business by the Autotype Company and other carbon printers, and they have produced suitable negatives for the work; whilst in portraiture, the negatives, being usually produced with a view to silver printing, are not necessarily the best for carbon work. Some of the portraits illustrating our work on pigment printing were equal to anything we have seen in silver.—Ed.]

But, in reply, I must remind you that Autotype aspires to an introduction among portraitists. They require proofs. Why not give them?

[Commercial companies generally occupy themselves most with that which pays best. The Autotype is no exception in this respect.—Ed.]

Certainly, at the exhibition of '69, a frame of Autotypes, printed from really fine negatives, were shown. The prints, however, were conspicuous for their lack of "pluck," and "washy" appearance.

[This is a question of taste. We heard them constantly admired by artists and men of the best taste.—Ed.]

With this remark, as far as I am concerned, the discussion ends, except new ground is broken; for, as you justly observed, arguments that rest on words only must remain subjects, not of proof, but of diverse opinions. I had hoped that my former remarks would have drawn out those who are so profuse in their denunciation of vested interests, as it would seem that whilst they upbraid obstinacy, they show nothing practicable to prove that photographers, by reject-

ing Autotype, are refusing a boon of unequalled capability. We have had enough of words. The time has arrived when something more substantial than words should be forthcoming.

[We must remind our correspondent that we have certainly had more work than words from carbon printers generally.—Ed.]

Having now "had my say," and relieved my conscience, I now shake hands, and consent to bury the war-hatchet, and remain, as before, yours truly,

W. T. BOVEY.

2, Charlton Villas, Park Road East, Acton, W.

CARBON VERSUS SILVER.

DEAR SIR,—It is difficult to imagine more cogent arguments against the continued practice of silver printing than the facts adduced by Mr. Bovey in his letter printed in your issue of January 20th. I have read none of the many articles upon the advantages of Autotype printing which has said so much to the disparagement of the old method of printing as Mr. Bovey's in that journal. We have heard much of the inherent properties of silver, its great affinity for sulphur unfitting it for use as a permanent pigment or colouring matter. It has been pointed out that we cannot put away even our utensils of solid silver, well protected by wrappings, in the secret recesses of our chests and safes, without their becoming yellow and tarnished by the sulphur compounds in the atmosphere. We have heard an eminent chemical and photographic authority, while suggesting means of rendering silver prints permanent, naively admit that that metal is one of the best tests of free sulphur with which he is acquainted; and we know that that element exists not only in the air of our dwellings, but in the very medium employed to hold or suspend the silver pigment in the formation of the picture. But all these sources, although productive of certain ultimate change, and essentially destructive to the picture sooner or later, act slowly. In a dry atmosphere, the sulphur is present in minute quantities only; so that, under favourable conditions, years may elapse before the action set up becomes visible and detrimental.

In the case, however, pointed out by Mr. Bovey—viz., the mixing of a "minute trace" of a solution essential to the production of the silver prints, at one stage, with the water employed in washing them at another—the action thereby set up, "catalytic" or otherwise, will ensure their perfect destruction in a few months; or will, at least, to use Mr. Bovey's only too familiar illustration, "unkennel as goodly a show of yellow streaks and jaundiced prints as ever disgraced a London photographer's show case, or a lady's gorgeously bound album."

If your readers have ever entered the back kitchen or cooped-up crib in which silver prints are only too often produced, or if in better localities—they will remember that in Mr. Bovey's late experience of "only too numerous" a batch of printers "their appearance varied from that of a cross between a dog-fancier and pugilist, to that of a swell out at elbows as well as out of luck"—they will see how little hope there is of that care and absolute cleanliness which alone can prevent the minute taint in question. A splashed sleeve, a dirty finger, an unbrushed nail—each is sufficient for the destructive taint. Nay, even were the rooms, vessels, and operators separated, it is not without the bounds of possibility that even a fly might communicate the cause of evil. A bee will impregnate a gourd with the pollen of one of another species situated miles away; a wading bird can stock a fish-pond; a fly will communicate putrefaction from putrescent to putrescible matter at a distance. Why not a "minute trace" of a strong solution of hypo in one room to a dish of water in another? At any rate, no honest photographer, after having had pointed out to him, in such forcible language, and with such illustrative facts, general and personal, the great probability of the destructive mixture occurring, should sell a silver print of any value without a guarantee that the fatal admixture has

not occurred during its production, or without a warranty for the absolute stability of that print for at least a few months. Yet, if even "care" is sometimes the cause of the evil, how can this be done conscientiously?

Depend upon it, some such assurance will be required if silver printing be continued. It is only the ignorance of the public with Mr. Bovey's facts which causes silver prints to be still sold; and it is their gradual acquaintance with them through the "yellow streaks and jaundiced" appearance of their albums which is the cause of the present declining state of photography.

Were the persons interested in Autotype printing as desirous of pushing their saleable wares as Mr. Bovey supposes, they should print his and similar articles, not in the columns of a journal devoted to technical matters, but for general circulation in our daily and weekly papers. It would then be seen that a system exists by which permanent prints can be undoubtedly obtained; and that, in the hands of photographers who can produce a good negative, such prints are admitted to be "superior." Now if, in addition to this, it were shown, and proof offered, that there are photographers who habitually produce good negatives, and who use the permanent process, there can, I think, be no doubt but that the public would profit by the information, and Mr. Bovey, and *id genus omne*, would soon follow in the rear of the successful portraitist. If it were admitted that the permanent pictures are not superior, or even barely equal, to silver prints—and no more has been said, even by persons whose prejudices or "vested interests" render them actively hostile, by word and pen, against the new system—we believe that, when supplied with the knowledge as to when and where such pictures could be obtained, these would receive the preference, inasmuch as the chief object of purchasing a photograph is to perpetuate the likeness of some dear friend or relative, and not to purchase a pretty toy, which may vanish, or pass into the stage of "yellow streaks and jaundice" in a few months, even when preserved in a glazed show-case or costly clasped volume. It is surely an odd way to perpetuate the existence of beloved but fleeting features by a memento which may, and probably will (crede Mr. Bovey), vanish in as many weeks as the original may live years!

At present it does not suit the Company's interests to do this: their standing advertisements merely show that there is no restriction to the use of the process. In the future it may suit their convenience to address the public, and instruct them, with Mr. Bovey's aid, on the shortcomings of silver, and the superiority of the Autotype, not only in permanence, but in other qualities; for assuredly the inferiority of the latter only exists in Mr. Bovey's imagination. His evidence, it will be observed, is merely hearsay evidence, and would not be received in a court of justice. Why through the columns of a public journal? Nor is the evidence unbiassed, apart from its unsoundness. There is a tone about Mr. Bovey's letter which clearly evinces a certain animus. It is transparent that Mr. Bovey was not sorry to have his preconceived opinions confirmed, and that the wish was father to the thought. It is not improbable that Mr. Bovey has "been fooled to his own bent." I can give him the names of commercial persons who practise the carbon process habitually, who use the fact extensively, but quietly, and most successfully, to attract clients, and disparage the silver prints of their neighbours, but who also equally habitually decry the process to enquiring friends. May not Mr. Bovey have met some such persons? Do his friends in trade always tell him the amount of their returns upon a given article, and "let him into a good thing" when they happen to secure one.

No amount of assertion, pro or con, can determine the relative value of the two opposing systems, the permanent and the fugitive. Does Mr. Bovey really wish to know the real merits of the two systems? If so, I shall be happy to meet him on any neutral ground in the presence of a few selected friends, for a day's printing in carbon and silver

respectively, from the same negatives, on the understanding that a report shall be made of the results, and the prints be exhibited. He will thus have an opportunity of really knowing the capabilities of the process he volunteers to decry. In the future his lucubrations on the subject in the public journals will then have the same value as his testimony to the causes of the "yellow streaks and jaundiced prints which disgrace (only too often) a London photographer's show-case, or a lady's gorgeously bound album, and which causes are, according to him (no mean authority), almost inevitable. At present such lucubrations are mere unaccredited gossip, unworthy of being repeated, still less of being recorded in the columns of a scientific journal.—I am, dear sir, J. R. JOHNSON.

CARBON FOR PORTRAITURE.

DEAR SIR,—It seems to me that answers to the following questions will materially contribute to solve the doubts respecting the probability of the carbon process superseding the present method of silver printing:—

1. Can carte-de-visite portraits be printed in carbon equal to silver prints?

2. Is it possible to make carbon vignettes with a clean white ground?

I have been quite unable to succeed in either of the above cases, and strongly suspect that this is the real cause of the general reluctance to adopt the new method of printing, as, of course, no photographer would be willing to adopt a process unsuitable for a large portion of his work.

If you have space, I should feel obliged by your insertion of this in the *News*.—I am, sir, yours obediently,

Tunbridge, January 30. P. A.

[Some of the finest card portraits we have seen were printed in carbon, and we have ourselves printed vignettes in carbon with perfectly clean whites.—Ed.]

DEVELOPING IN DISHES.

MY DEAR SIR,—As I do not know Mr. England's address, will you kindly allow me the use of your columns to cordially thank him for his reply to my question on dishes for development?—I am, yours faithfully,

OXONIENSIS.

THE LATE THOMAS ROSS.

DEAR SIR,—Being the only surviving member of the family of the late Andrew Ross, optician, I deeply regret not having seen the announcement of the death of my brother in the last number of your journal. The only one that it has appeared in is the *British Journal*, on page 20, and he is mentioned as Mr. Ross, of Kilburn, not Thomas Ross, optician. If you will kindly insert in your next number that my brother, Thomas Ross, optician, of 2, Featherstone Buildings, and 7, Wigmore Street, died at his residence, 1, Upton Villas, Kilburn, on the 16th of December last, after a short illness, I shall feel much obliged.—I am, dear sir, yours truly,

SARAH S. ROSS.

5, Harringay Villas, Green Lanes, N., January 31st, 1871.

[We refrained from any announcement of the death of Mr. Thomas Ross in deference to the wish of his family, as especially expressed in a message sent from his house, not from neglect or indifference; indeed, the obituary notice was partly written when we received the message, which we felt we had no right to disregard.—Ed.]

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE first monthly meeting of this Association for the present year was held on Tuesday evening, the 31st ult., at the Free Library, William Brown Street.

Arranged on the tables and around the room were a large number of photographs taken by the members during the past

year. Many of these were exceedingly beautiful, and a small print by Mr. E. L. Williams, Jun., "On the Sands," attracted much attention, many members expressing a wish that prints could be obtainable.

Mr. HIGGIN showed a number of *Art*, illustrated with pictures printed in printer's ink on a printer's press from negatives.

The SECRETARY exhibited an enlargement by Mr. Winstanley, of Manchester.

The minutes of the last meeting having been read and confirmed,

Mr. JOHN HENDERSON, on retiring from the office of President, stated that the Society was still in a flourishing condition, the number of members being about the same as last year. The following papers had been read:—"On the Infusion of Quassa as Applied to Dry Plates," by Mr. J. N. Sladdon; "Photography as Applied to the Purposes of Education," by Mr. T. Higgin; "Carbon by Single Transfer," by Mr. J. A. Forrest. There had also been a lantern exhibition, by Mr. Lewis Hughes. Unfortunately, the weather had not been favourable on the excursion days—those to Furness Abbey and up the Weaver River being the most agreeable. He (Mr. Henderson) also alluded to the loss the Society had sustained by the retirement of Mr. Guyton, their late Secretary, and concluded by thanking the members for their courtesy towards him during his term of office as President.

Mr. THOMAS HIGGIN, the newly-elected President, then took the chair.

Messrs. G. R. Isbern and W. H. Tyerman were elected members of the Association.

A vote of thanks was passed to Mr. Edwin Flukes, of Bath, for his present to the Society's album of three twelve by ten views of Wells Cathedral, which were much admired.

Messrs. Wilson, Green, and Henderson were the appointed judges to award Messrs. Robinson and Cherrill's prize for the best year's work. They made the following report:—

"The Sub-Committee appointed to decide on the respective merits of the photographs exhibited for competition this evening have found special difficulty in making their award, owing to the very diverse character of the two best collections, viz., those of Mr. T. Higgin and Mr. E. Leader Williams, Jun. After careful inspection and consideration, they award the palm for the best year's work to Mr. Higgin for his large and beautiful collection of microphotographs, and only regret it is not in their power to bestow a second prize on Mr. Williams for his very excellent collection of landscape and figure subjects. Prints exhibited by Mr. Higgin, 82; Mr. Williams, 39. There was no competition for the smaller prizes."

The PRESIDENT then read his address, which will appear in our next.

A vote of thanks was then passed to the President for his able address, proposed by the Rev. T. B. Banner, seconded by Mr. J. A. Forrest.

The Rev. T. B. BANNER hoped that the members would follow many of the suggestions proposed by the President. He thought that, looking at the splendid productions before them, it would be advisable that, instead of buying the presentation print of the year from a professional photographer, they should prints taken by some of their own members, for he was quite sure some of the specimens exhibited that evening could not be surpassed by any professional.

Mr. GREEN offered to take a photograph suitable for a presentation print during the year, if other members would do the same.

Mr. J. A. FORREST remarked that May would be the best month for taking them, as it would give time for printing the requisite number of copies. The arrangement was left to the Council.

Mr. FORREST called attention to the fact of there being a room in the building, fitted up with all the appliances for photography, which he thought might be obtained for the use of the members.

Messrs. Wilson and Forrest were requested to experiment and report on the carbon-printing process.

The Excursion Committee were desired to report, at the next meeting, the most suitable places to visit, so that excursions might take place early in the year.

A lantern exhibition by Mr. E. L. Williams was announced for next meeting, on the 28th of February, to which members were invited to bring their friends.

The meeting was then adjourned.

Talk in the Studio.

How THE "TIMES" WAS SENT TO PARIS.—Attempts to establish a ready communication between the beleaguered inhabitants of Paris and their relatives and friends beyond the German lines have given rise to many contrivances which are not unlikely to make a new era in the history both of aeronautics and photography. Among them may be mentioned the ingenious device by which the matter of two whole pages of the *Times* has been transmitted from London to Paris. This has been accomplished by photography. Those pages of the paper which contained communications to relatives in Paris were photographed with great care by the London Stereoscopic and Photographic Company on pieces of thin and almost transparent paper, about an inch and a half in length by an inch in width. On these impressions there could be seen by the naked eye only two legible words, the "*Times*," and six narrow brown bands representing the six columns of printed matter forming a page of the newspaper. Under the microscope, however, the brown spaces become legible, and every line of the newspaper was found to have been distinctly copied, and with the greatest clearness. The photographs were sent to Bordeaux, for transmission thence by carrier pigeon to Paris. When received there they were magnified, by the aid of the magic lantern, to a large size, and thrown upon a screen. A staff of clerks immediately transcribed the messages, and sent them off to the places indicated by the advertisers. The success of this experiment gives rise to the hope that the new art of compressing printed matter into a small compass will not stop here. If a page of the *Times* can be compressed into a space little larger than that occupied by a postage stamp, the matter of an octavo volume might be made to cover not more than two of its own pages, and a library could be reduced to the dimensions of the smallest prayer book. What a relief it would be to the learned persons who frequent the library of the British Museum if, instead of having to make fatiguing journeys from letter A to letter B of the ponderous catalogue of books, they had its many hundred volumes reduced to a space a yard square, over which a microscope could be hurriedly passed. Such suggestions are now occupying the thoughts of photographers.—*Times*.

A MORTUARY ALBUM.—Mr. W. H. Russell, writing from the German headquarters at Versailles in the *Times*, says:—"After dinner last evening there was produced at headquarters a massive album, as large as a quarto edition of the Bible, and elaborately bound in embossed leather. In the centre of the cover were the arms of Saxony; on the four corners is the insignia of the iron cross. The officers stood round the table as the album was opened, and I thought it contained scenes in the war; but on the pictures being exhibited, I saw that each was a large-sized photograph, and I was informed that it was the likeness of a Saxon officer killed during the present campaign. Portrait after portrait was taken out for a quarter of an hour. It was a sad sight. Most of the originals were very young men when they fell, and had been the comrades of the officers who were now, and more than one of them with wet eyes, gazing on the portraits. I expressed my surprise at the number of these mortuary photographs, and was told that they represented only one half the officers who had fallen. Another such volume would be filled before the sad series would have been completed up to the present time. Short of seeing the dead bodies of all these victims, nothing could have brought home to one's mind with more painful vividness the widespread mourning which this war must be causing in Germany. Be it remembered that those gentlemen were all commissioned officers in a single Army Corps. What if we had the portraits of all the rank and file killed in this same corps! What a lesson might be learnt from such a gallery!"

HOME PHOTOGRAPHS IN CAMP.—A letter from the special correspondent of the *Daily News* at the German headquarters gives a graphic account of the universality of home photographs amongst the German soldiers. He says:—"I never knew a German officer or soldier who was a family man that did not carry about with him photographs of the wife and the children. By this time the cartes are getting dirty and thumb-marked, for they are had out for inspection and admiration very often. You will see a couple of officers in the casino, or at the mess table, interchanging sights of photographs, and then comes a gossip about the children's ages. I have watched the growth of a warm friendship between two gentlemen I have the pleasure to know, the first link in which was the discovery at one of these quiet talks over the pictures, that one had a

boy and the other a girl, who were born on the very same day of the very same year. I have seen two huge hairy sentinels at a double post far to the front exhibiting one to the other the gallery of family portraits, fetched out of a sweat-besmirched pocket in the breast of the tunic. This afternoon I was standing by the white house on the hill behind Andilly, trying, with but little success, to get a glimpse of the firing through the fog bank, when there joined me two or three men of the 26th Regiment, and we naturally fell into conversation. Presently, as I turned to go, one of them remarked, in perfectly good English, "Heigho! I wish this weary war was over, and I back in New York." The man had been for some years earning his two dollars a day as a house-painter in New York, and had got married and begot sons and daughters. When the war broke out he threw down his brush, shipped himself, wife, and daughter—the boys were dead—on board a North German Lloyd steamer, and had fallen into his place in the ranks with no more fuss, or consciousness of extra patriotism, than if he had come for a holiday. Of course, out came the photographs—he carried them, to be handy, inside the folded cuff of his great coat. "Ah! isn't she a fine woman just; and isn't the girl a beauty?" He was proud of his belongings, and had no stuck-up rotteness about owning up to his pride. As I walked home, after leaving him, I fell a pondering on the differences in national idiosyncracies, and there came to my recollection the pictorial contents of sundry French officers' knapsacks that German officers spoke of after Sedan and Metz, their noses in the air as if they inhaled a foul stink."

PRISONERS REFUSING TO BE PHOTOGRAPHED.—Recently a gaol session was held at Liverpool, when the visiting justices drew attention to the fact of two prisoners, who had been committed for trial, refusing to have their photographs taken, for the purpose of having them forwarded elsewhere, that their antecedents might be known. These men had not been found guilty, and therefore the officials of the gaol could not force them to be photographed. The visiting justices thought that the Home Office should be consulted with as to the desirability of forming some resolution of which the Home Secretary might approve, by which it would be made compulsory on all prisoners to be photographed, and could be punished on their refusing. It was resolved to communicate with the Home Secretary on the subject. The *Daily News* thus comments on the subject: "How far it is permissible to introduce torture by photography into our penal code, and to exclude other and far less trying forms of punishment, is a question more easily put than answered. It has been decided, however, that, in the interests of the State, convicted wrong-doers shall be photographed, and it is said that the photographs of these gaol-birds have proved very useful in furthering the ends of justice. So well pleased are the authorities of the Liverpool Gaol with the system, which enables the countenances of criminals to be limned with perfect fidelity, that they wish to extend the practice, and to get all the prisoners photographed who pass through their hands. Two prisoners having refused to submit to the process, and the authorities being without power to apply compulsion, an attempt is now being made to obtain the requisite authorization from the Home Secretary. Now, it must be remembered that not every prisoner is a criminal. A prisoner in gaol awaiting his trial is innocent in the eye of the law. He has done that which makes him the subject of strong suspicion, but he may be able to show when the trial comes that the suspicions were baseless. To photograph such a prisoner may sometimes contribute to bring about his conviction; yet it may likewise redound unfairly to his prejudice. When his innocence has been demonstrated, it is the reverse of satisfactory to think that his photograph has been extensively circulated by the police. This innovation in the accustomed mode of dealing with unconvicted prisoners is so important as to deserve full and careful consideration before receiving official or Parliamentary sanction."

A PHOTOGRAPHIC PRESENTATION.—The members of the City Police Band have presented Inspector J. R. Foulger, the president of the band, with a life-size portrait of himself. The presentation took place at Mr. Making's, St. Paul's Churchyard. The artists were Messrs. D. B. James and Co.—*City Press*.

To Correspondents.

MORRIS BEACFORT.—Apply to the Autotype Company, 36, Rathbone Place, for carbon printing; and to Mr. Henderson, 49, London Bridge, for printing in a ceramic surface in vitreous colours.

CHLORIDE.—A mixture of equal parts of powdered carbonate of soda and carbonate of potash is an excellent flux for chloride of silver. Mix this flux, quite dry, with an equal proportion of chloride of silver, mixing them intimately in the crucible. Other residues require other fluxes; see some of the many articles we have published on the subject. 2. Pure metallic silver is worth about 5s. 6d. per ounce.

J. MALEB.—It is probable that you will find both your baths in good condition. They will not injure by keeping in a bottle.

C. G. F.—The masks in the advertisement in question are, as you will see, announced as procurable of all photographic dealers, from which it is presumable that the manufacturer does not wish to supply them direct to photographers, but through dealers.

W. W.—A toning bath will generally ripen more quickly from exposure to the atmosphere. 2. Your still will doubtless answer well. 3. It is illegal to employ a still for any purpose without communication with the Inland Revenue authorities, but how far the matter is pressed we cannot say. 4. Your general ideas on the studio question are correct: 15 feet of side-light will be sufficient.

D. G. (Subscriber).—The sandy-looking deposit on the negative is generally due to the presence of excess of iodide of silver in the nitrate bath. Dilute the bath with twice its bulk of distilled water, filter out the turbidity, and then add nitrate of silver to make the solution of the proper strength.

THE REV. S.—Full details of the modifications in the collodio-albumen process, proposed by Petschler and Mann, in the *PHOTOGRAPHIC NEWS*, Vol. IV. We do not remember any other place with certainty. 2. The keeping qualities of tannin plates are uncertain. 3. The best dry plates for keeping qualities are those prepared by Mr. R. Mannors Gordon's gum-gallic process, or the collodio-albumen process with the final wash of gallic acid. Plates by either of these processes may be kept several weeks—or even months—before and after exposure, without injury.

F. G. N.—Liquid glue is altogether unsuitable for mounting photographs. It is made by adding acid to an ordinary hot solution of glue, and stirring well together. The result is, that the glue remains fluid on cooling, instead of setting. It is very useful for many purposes, but should not be used for mounting photographs.

GLENAVONIENSIS.—The most probable supposition is, that the film had dried round the edges, which, in hot weather, with some samples of collodion, rapidly takes place. This would prevent the bath solution permeating the dried portion. It is possible that you were using a new bath which had not been properly iodized, in which case the bath would dissolve out the iodide of silver first formed, and as this generally commences at the edges, they might be left transparent from that cause. Light entering the bath could not produce such an effect.

J. TURNLY.—The solution used by M. de Constant for strengthening the image, after faulty development, is three grammes ammonia-sulphate of iron, three grammes of sulphate of copper, and three grammes of citric acid in three and a-half ounces of water. We shall shortly publish fuller details of his process. 2. If the alcove background be made of green wood, and kept in the open air, it will be difficult to avoid shrinking, so as to show the divisions between the pieces of wood; but if it be made of seasoned wood, in as many narrow pieces as possible, and be kept fairly from the damp, it may be covered with brown paper, and then painted. 3. In using mercury as an intensifying agent, we have generally first applied the mercury solution, and then the iodide solution.

G. A.—The card vignette in an opal aperture, with grey border, is very pretty, but not new. The photo-micrograph is very good.

MARS.—The best method of getting black tones on developed opal prints is by toning them with a moderately strong neutral solution of chloride of gold. They should not be too light at first, as gold toning slightly bleaches the image. The formulae given by Mr. Burgess for producing eburneum prints will give good results on opal glass. 2. Gelatine negatives are not common. The mixture of gelatine and bichromate is not sufficiently sensitive for images in the camera. 3. The spottiness and dullness which sometimes occur in collodio-chloride prints on opal glass is generally a result of allowing the film to dry spontaneously, and allowing too long a time before it is printed after coating the plate. We prefer drying the film before the fire as soon as it is set, and then printing as soon as it has cooled. 4. Hard sized papers or cards give very good results with collodio-chloride without preliminary preparation. Ordinary photographic paper should be first sized with arrowroot, and then rolled.

G. LLELWYNS.—We should recommend No. 2. We do not know of one for sale at present. Look amongst the advertisements on the third advertisement page. 2. It is impossible to say which State you would succeed best in, as so much depends on circumstances. See Mr. Wilson's recent remarks on the subject. We should recommend you to endeavour to get an engagement as operator for a time, before commencing the business, and so get an opportunity of looking about you before you settle in any place. In the States there is an immensely wide range of country to choose from.

J. MARTIN.—Received.

A NEW PHOTOGRAPHIC AGENT—INDIA-RUBBER.

A VERY brief and modest article contributed to our YEAR-BOOK by Mr. J. W. Swan describes a possible method of producing photo-lithographic printing surfaces by means of india-rubber, which is sufficiently sensitive to the action of light to be available for the purpose in question. The process described is suggestive of much more than is indicated, and has, we believe, in experimental trials, given, in Mr. Swan's hands, considerable promise of much wider possibilities than he has entered into in the article in question, and which, to make our further remarks clear, we will quote. Mr. Swan says:—

“I have found that caoutchouc is so altered by the action of light, that whereas in its natural state it does not communicate to a clean lithographic stone an ink-imbibing quality, by being strongly pressed into contact with it, after being exposed to a few hours' sunshine, it will, by strong pressure, ‘set off,’ and give to a lithographic stone a strong affinity for ink.

“The discovery of this fact provides the means of an extremely simple photo-lithographic process. It is only necessary to coat paper with a solution of caoutchouc, and, after the thorough evaporation of the solvent (which, in my experiments, was benzole), expose the sheet (under a negative) to sunshine, and it is at once in a condition to transfer to stone, in the usual way, the greasy image which the light has engendered.

“The caoutchouc with which I experimented was in the condition known as ‘masticated rubber.’ I mention this because I think it is not unlikely that the comparatively great sensibility to light which I found it possessed may be a peculiarity of caoutchouc *in that state*. I have not experimentally verified the idea of the peculiar sensibility of masticated over native caoutchouc, but theoretical considerations suggest the probability of its correctness.”

Professor Seely, of New York, some years ago, pointed out that the compound of india-rubber and sulphur employed in producing vulcanized india-rubber was sensitive to the action of light, and that light produced a similar result as heat in the process of vulcanizing. He suggested two or three methods of utilizing the property in question for producing images by the action of light through a negative on a layer of india-rubber and sulphur. After exposure the layer, being treated with a solvent, became swollen in the protected portions, the sunned parts having become impermeable to the solvent. Casts of the image in relief might, it was suggested, be secured. If the sunned film were treated for a moment with a solvent, it was suggested that it would become sufficiently sticky to permit the adhesion of a black powder, and so yield a picture. So far as we know, these suggestions were never

carried out, Mr. Seely himself remarking that he recorded the possibilities in question rather as matter of scientific interest than for the probability of practical value which they possessed.

Without, we believe, having any knowledge of the experiments of Professor Seely, Mr. Swan, in the course of his experiments in carbon printing, discovered the fact that india-rubber was decidedly sensitive to the action of light, and that some very curious results arose out of this fact. He mentioned the matter to us some years ago, as one still in course of experiment, not to be mentioned until further worked out. As other pressing engagements have driven the matter aside from time to time, we are now at liberty to suggest the subject to other investigators, as one which will probably repay experiment.

One of the earliest peculiarities of india-rubber which Mr. Swan noticed was, the fact that a film of this substance having been exposed to light ceased to be soluble in the ordinary menstrua—such as turpentine, benzole, and similar fluids—but it had become soluble in another fluid, which had no action upon it in its unsunned state, namely in alcohol. Hence, a film of india-rubber exposed under a negative—or, rather, under a transparency—and treated with alcohol, having become soluble in those parts upon which light had acted, and in proportion to the action of light, would yield a picture with all the gradations of the negative represented by the undissolved portions of this india-rubber. If a suitable pigment or other colouring substance were mixed with the solution of india-rubber used in forming the film, the picture would be formed of such colour as imprisoned by the insoluble india-rubber. As in this case the image consists of the portions in contact with the paper which were at first, and continue throughout the process, insoluble, the portions of the film removed by the alcoholic solvent being those acted upon by light—and not the portions protected from light—as they are in ordinary chromo-gelatin carbon process, it follows that the film does not require to be exposed from the back, nor is any transfer required before development. The india-rubber and pigment coated paper would be exposed with its coated side in contact with the negative, and developed with alcohol on the same side.

To what extent the principle involved in these changed conditions of solubility, as the result of the action of light, may be carried, yet requires to be ascertained. It has been long known to telegraphic engineers that india-rubber, when used as an insulating substance, rapidly perished under the influence of light and air, but was much more durable when protected from their action. Mr. Spiller has shown that india-rubber used in making waterproof felting for ammunition purposes gradually became oxidized, losing its elasticity, and acquiring the character of a friable resin. It was reserved for Mr. Swan to discover that these changes

were due to the action of light, and to note that a changed character, in respect to solubility, accompanied the other visible changes.

Before leaving the subject, we may mention another possibility in connection with the use of the photographic india-rubber which Mr. Swan has mentioned in a recent letter, and which, it will be seen, has close analogies with the lithographic process he has described. In the plan to which we refer, Mr. Swan proposes that the portion which has been rendered soft or soluble by the action of light shall form the picture instead of the insoluble portion. In this case a layer of india-rubber, or india-rubber and colour, would be exposed under a negative, and then placed in contact with a sheet of paper moistened with the solvent, and submitted to pressure like an engraved plate, and an image thus printed on the sheet of paper. The subject is new, and the material comparatively untried; but here are, we think, probabilities indicated which make it fully worthy of further investigation.

FORMULÆ IN AMERICAN STUDIOS.*

NAPOLÉON SARONY'S FORMULÆ.

FROM Mr. Napoleon Sarony's gallery, Mr. B. T. Richardson gives the following details:—

Cleaning Glass.—Soak the glass several hours in a strong solution of common washing soda, then wash thoroughly under a running stream of water with a clean sponge, and finally rinse with care, and place the glass in a rack to dry. Before using, clean with alcohol and cotton flannel.

Negative Silver Bath.—Forty grs. nitrate of silver to the oz. of water, iodized with iodide of silver, and slightly acidulated with nitric acid.

Remarks.—A bath that is well iodized with me gives better results, clearer, and more definition than one neglected in this respect. When the bath wants renovating, boil it down to dryness, redissolve, and add iodide of potassium in proportion as 2 grs. for each oz. of nitrate of silver it contains. Also add a few drops of nitric acid, say 5 drops to the gallon of solution. By this management of my bath I always find it to work from the word "Go!" Never allow the bath to run down. Be diligent, watchful, and extremely careful. When it calls for food, give it something to eat, and it will never go wrong.

Negative Collodion.—Ether and alcohol, equal parts; iodide of ammonium, $4\frac{1}{2}$ grs.; bromide of potassium, 2 grs.; cotton, 5 to 7 grs. Iodize the ether and alcohol, then add the cotton.

Remarks.—Wash the cotton thoroughly in liquid ammonia one part, water four parts, and let it dry before using it; or, if necessity requires its immediate use, wash it in alcohol by saturating it two or three times, and squeezing it out each time. Collodion made in this way should mature at least ten days before it is used.

Developer.—Water, 64 ozs.; protosulphate of iron, 4 ozs.; acetic acid to suit circumstances.

Remarks.—Much depends upon having the developer harmonize properly with the free silver on the plate. I often find a little more or less acid, or a little stronger or weaker iron, very beneficial. In fact, a man must use brains withal, and adapt himself to circumstances. In warm weather, less strength of developer is preferable. The fineness and gradation depend much on the developing. Under or over developing will entirely change the character, and almost destroy the beauty, of the negative.

Re-developer.—Water, 1 pt.; citric acid, 45 grs.; pyrogallie acid, 20 grs.; to which add a few drops of negative bath as it is required for use.

Remarks.—I rarely find it necessary to re-develop my life negatives, aiming to avoid it when I can.

Fixing Bath.—Water, 4 qts.; hyposulphate of soda, 1 lb. or more; cyanide of potassium, 1 oz.

Remarks.—Owing to the fact that this bath soon becomes more or less saturated with silver, it is necessary that it should be replenished, or strengthened often with hypo, and changed entire every few days.

Mr. Charles Hoffman gives the printing details as follows:—

Sensitizing Silver Solution.—Water, 1 oz.; nitrate of silver, 50 to 55 grs.; nitric acid, to render it very slightly acidulated. Float 1 minute, and fume 15 minutes.

Remark.—Float less time in warm than in cold weather.

Toning Bath.—Water, 3 qts.; common washing soda, $\frac{1}{2}$ lb.; and as much chloride of gold as the prints to be toned will require.

Remarks.—The tone of the prints will depend entirely upon the length of time they are allowed to remain in toning. If a warm sepia be desired, tone light; if brown, tone more; if blue be required, tone accordingly.

Hypo Fixing Bath.—Water, 12 qts.; hyposulphate of soda, 2 lb.

Remarks.—Never allow the prints to remain in fixing bath after they have become clear and brilliant.

KURTZ'S FORMULÆ.

FROM the studio of Mr. Kurtz, Mr. Elbert Anderson, with whose name our readers are favourably familiar, writes the following details:—

Cleaning the Glass.—The manner in which we clean our glass for negatives is to immerse them several hours in a strong solution of common washing soda, then rinse off and place them in nitric acid 1 part to water 2 parts. After remaining in acid from one to two hours, wash thoroughly under a stream of water, rubbing the glass with a clean sponge until all deposits are removed; then rinse well, and after the water has partially dripped off, proceed at once to coat the side that is intended to receive the impressions with the following preparations:—

Water, 24 ozs.; albumen (the white of one fresh hen's egg) so thoroughly beat that the vessel containing the froth may be turned bottom upward without spilling the substance. Let the froth stand over night to subside. In the morning add the clear liquid to the water; shake it thoroughly, then filter, and it is ready for use. Pour as much of this on the glass as will flow it nicely, and run the surplus into the sink; then place the glass on nails to dry, free from dust. As soon as the albumen is thoroughly dry, the glass is ready for use. Glass prepared in this way will keep for months without deteriorating.

Negative Bath.—Water, 1 oz.; nitrate of silver, 40 grs.; iodized with iodide of silver, and slightly acidulated with nitric acid.

Renovating the Bath.—Boil it down one-half or more, then dilute with water to its proper strength, and filter. This operation must be repeated as often as the bath becomes foul. I never add new silver to an old bath. If the amount of solution require increasing, I add from another old bath that is in good working order, or the old solution may be added before boiling, and all boiled down together.

Negative Collodion.—Ether and alcohol equal parts; iodide of ammonium, 4 grains; iodide of cadmium, 2 grs.; bromide of potassium, 2 grs. It will mature in one or two days suitable for use.

Developer.—Water, 16 ozs.; protosulphate of iron, 1 oz.; acetic acid, 1 oz.; alcohol, $\frac{1}{2}$ oz., if the developer does not flow without it. Avoid its use when not needed.

Re-developer.—Citric acid, 40 grs.; pyrogallie acid, 40 grs.; water, 24 ozs. I do not find occasion to re-develop very many of my life negatives, preferring them without, unless a negative is weak, and re-development is necessary.

Fixing Solution.—Water, 1 gal.; saturated with hyposulphate of soda, to which add 1 oz. of cyanide of potassium.

Mr. Richard Howe gives the printing details of the same establishment, apologizing, by the way, for some delay, on the ground that he has the printing of from

* Continued from p. 56.

sixty to eighty negatives daily under his charge. His method is as follows:—

Silver Bath.—Water, 1 oz.; nitrate of silver, 60 grs., slightly acidulated with nitric acid; float one minute in warm and two minutes in cold weather. Fume from 15 to 20 minutes, according to the temperature of the atmosphere.

Toning Bath.—Water, 32 ozs.; acetate of soda, 15 grs.; chloride of sodium, 15 grs.; chloride of gold, 7 grs.; neutralize the gold with bicarbonate of soda before adding it. Vary the tone of the prints by allowing them to remain a longer or shorter time in the toning solution.

Fixing Bath.—Water, 6 oz.; hyposulphate of soda, 1 oz.; continue the process of fixing until the paper has become clear, and the picture brilliant, and no longer.

It will be noted that all the formulæ have much in common, and that none vary much from those in general use in this country. In three of the establishments, it will be seen that common washing soda is employed to neutralize the toning bath, and that the proportions of gold and soda are added by rule of thumb, a plan only admissible on the assumption that the workman possesses great skill and experience.

MODES OF LIGHTING.

The mode of lighting, being, at least, as important as the chemicals, is also described in each case, as follows:—

C. D. Fredericks and Co.—The light used in this establishment in the production of the test negative is wholly a top light, slanting to the west at an angle of about 40 degrees, and is 16 feet square. The lower portion of the light is about 7 feet from the floor of the skylight room. Notwithstanding the light is wholly admitted from the top, the invincible Hugh O'Neil so guides the vertical pencil by using screens and reflectors, as to produce Rembrandt and other shadowy effects with all the power and brilliancy imaginable.

Gurney and Son use a top and side light combined. The top light fronts nearly to the north, and lies on an angle of 60 degrees, and is 16 feet square, with a side light extending to the floor, and the same length as the top light. The height from the floor to the top light, at its lowest extremity, is about 8 feet. In producing single sittings, much of the light is shut out with curtains, and screens and reflectors are used in producing shadowy effects.

W. Kurtz's main light—the one used in making the test negative—is facing to the north on an angle of about 45 degrees, with side lights combined. Mr. Kurtz has somehow a peculiar faculty in the management of sun-beams. He has a way of his own in making light shine in the very spot it is wanted, by the use of shades, screens, reflectors, and counter-reflectors. Beyond all question or doubt, he possesses a skill in the distribution of light on his subjects superior to the most of even those considered first-class photographers. His method of managing light is highly worthy the consideration of every photographer.

N. Sarony and Co.—The light used in this establishment for producing the test negative nearly resembles that of C. D. F. and Co.'s, fronting to the north instead of west, and somewhat lower and steeper in its angle. Very few photographers in this or any other country have been able so to manage light in their studios as to completely model the entire faces of their subjects in portraiture as he has done. He resorts but very little to screens and reflectors, aiming mostly to pose his subject in unreflected and unobstructed light.

Two of the studios, it will be noted, have what is termed top-light only, resembling that in the studio of Mr. T. R. Williams, but which is, by its construction, position, and management, practically used as a high side-light. Mr. Kurtz, who is one of the ablest masters of the art of lighting in the photographic profession, makes especial use of side-light.

ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

THE FORTHCOMING INTERNATIONAL EXHIBITION—APPRENTICESHIP IN PHOTOGRAPHY—THE FORTHCOMING TRIAL BETWEEN CARBON AND SILVER PRINTING—THE COPYRIGHT DISCUSSION—EXPRESSION AND LONG EXPOSURE—COLLODIO-BROMIDE.

THE repeated allusions and announcements in various journals during the last few weeks, having reference to the forthcoming international exhibition, the first of an interminable annual series, give assurance that, notwithstanding the untoward state of events on the continent, the exhibition experiment has to be proceeded with. I hope its success will be greater than many of the indications seem to promise. France and Prussia cannot contribute, and the absence of two such nations from a representation of the fine and industrial arts must of necessity cause a sad hiatus. In this country I do not hear any very enthusiastic anticipations expressed. Many houses connected with industrial art seem to regard it with distaste: they must exhibit to maintain their status, and the result, they seem to think, will scarcely be worth the cost. How it will be with photography it is difficult to guess. A few of the best photographers will doubtless contribute, but I fancy that the photographic contributions will not be extensive. Is it not more than time, by the way, that photographers should be made acquainted with the names of the gentlemen forming the committee of selection to whose judgment their works must be submitted for approval before they can be exhibited? Photographers must send in their contributions in less than a fortnight. Is it fair that they should do so in the dark as to the tribunal to which such works will be submitted? Is there any reason for secrecy in such a matter? Rumour has whispered that one distinguished amateur would form the committee, and issue his fiat without consultation or control. I do not doubt that it would be both honest and competent; but still, as a matter of respect to photographers, I am glad to remember that you have already announced that the committee would consist of three gentlemen, whom you appeared to know and approve.

Your esteemed American correspondent, I notice, has recently referred to an important question which has yet received little attention amongst photographers. I mean the subject of apprenticeship. At present by far the greater number of professional photographers are self-educated in their art: they have "picked it up," having commenced life with some other business or profession. As a rule, men who thus "pick up" an art have some original fitness or proclivity for its exercise. But whence come into the art such men as Mr. Bovey recently described as familiar types of the photographic printer—the men who varied in appearance from that of a cross between a dog-fancier and a pugilist, and a scedy out-at-elbows swell? These never became photographers from natural fitness or affinity: they were never apprenticed to the art. Whence came they, then? Perhaps the source is not difficult to trace; but it suggests the importance of the apprenticeship question. I fear a large number of those who have become photographic assistants of late years have first come into contact with the art as lads hired to clean glasses, and assist in the more mechanical departments of the studio, dark room and printing room. These also "pick up" some knowledge of the art, and eventually commit their fortunes for life to it; not because of artistic or scientific tastes and capacity, but because it seems to present the easiest and most handy means of making a living. If a system of apprenticeship were organized, it would remedy much of this. The apprentice who is specifically taught, and graduates in his art, would have in his indentures a charter to practise as a skilled man, and give him a distinction from the mere pretender. This is a question which touches the future

more than the present, but still it is worthy of thought now.

Reference to printing reminds me of the recent carbon discussion. I refer to it with reluctance and hesitation, as I take it for granted that you, in common with many of your readers, are sick of it. I only mention it to say how glad I am that the dreary war of words finishes with a prospect of a practical test, and to add a suggestion: it is, that Mr. Woodbury and Mr. Edwards should each have an opportunity of printing from the same negatives as are used in the carbon and silver trial. If half a dozen varied subjects from different kinds of negatives were produced by the methods in discussion—silver, carbon, and mechanical printing processes—and made accessible for examination by photographers, they would be more valuable, and certainly more interesting, than any amount of word-fencing or dogmatic expression of opinion. Examination of specimens possibly may change views and produce conviction. I doubt whether discussion ever does.

Notwithstanding the conviction just expressed as to the comparative uselessness of discussion, I shall be very willing, if the Editor permit or desire, to point out some of the errors of Mr. Cunningham, as he challenges me to do. But I should hesitate, without special permission, to do anything to protract a correspondence which has already been spuu out to a wearying extent. At any rate, it will be wise to wait until Mr. Cunningham is quite done before pointing out his errors.

Mr. Cocking, in his paper on expression and long exposure, struck a vein well worth consideration. An instantaneous exposure would be of comparatively little value in securing good expression, unless the moment could be seized when the sitter was unconscious of the operation. The great difficulty is, however, to get unconsciousness, and get rid of the "put-on" expression. The masters in our art often have the happy faculty of placing the sitter at his ease by inspiring confidence. I remember once being present in the studio of Mr. H. P. Robinson, when a lady asked, with nervous apprehension: "How am I to place myself, and what shall I look at, and where must I put my hands? I know you cannot make a nice portrait if I sit awkwardly." A reassuring smile accompanied the quiet answer, "Pray hold me responsible for all that, madame, and don't give yourself the slightest anxiety." I have understood that Mons. Adam-Salomou has a singular skill in inspiring confidence in the sitter. Now, in a long exposure, supposing the sitter to be firmly and easily placed, the first nervous feeling of apprehension has time to pass away, and a calm natural expression to succeed it. I give the opinion with hesitation, but I am not sure that a portrait produced in a sitting of three minutes would not be better than one produced in a minute; but I must admit that I think three seconds would be better than either. I have heard it said that a celebrated lady amateur once explained that her portraits were easy and successful because the sitting was so long that it scarcely mattered if the sitter left his seat and took a stroll round the room to stretch his legs during the sitting. But, of course, that's a fable.

The subject at the last meeting of the Photographic Society was full of interest. The principle of the collodion-bromide process always strikes me as so beautiful and philosophical that I wonder it has been so little practised. The varying conditions of sensitiveness appear to constitute the drawback, and, unless it can be overcome, must always be a barrier to its general use, for uncertainty in the matter of sensitiveness is, I think, of all faults, the worst in a dry plate, inasmuch as no preliminary test can be made in the field. In the wet process, if the first shot fail, a second is easily tried; but with a dry plate the result, if not certain, often causes irreparable loss.

AMERICAN CORRESPONDENCE.

PHOTOGRAPHY ON MOUNT WASHINGTON—THE USE OF WARM WATER IN TONING.

As I have previously communicated to you, a party of photographers, geologists, &c., proposed to spend the winter on the top of Mount Washington, N.H., the highest and grandest of New England's crown—the White Mountains. This, as you may perhaps guess, is a bold undertaking, for in September I have known icicles six inches long to hang upon the telegraph wires on the summit, and the wind to be of that velocity that one could scarcely stand if he had even the desire to go outside the rough but comfortable "tip top house" and make the experiment. These men of science, however, made every preparation to carry out their project, and are now comfortably quartered in a room in the railroad depot on the summit, almost a mile and a half above the sea. Coal, provisions, clothing, snow shoes, axes, &c., with photographic and meteorological apparatus, were amply provided, and a telegraph operator supplied by the Government to operate the telegraph, which was specially laid for their convenience. This telegraph is their only means of communication with the world below, except occasionally, when a hunter, or someone else, out of curiosity to see the party, makes them a visit, and, on his return, carries such letters to Littleton as they may want to send, and there posts them. By the latter means I have just received a letter from Mr. A. F. Clough, the head of the photographic department, and I give you a few extracts therefrom as another proof of the indefatigability of the photographer, when he feels that even by privation and hardship he can win fresh laurels to crown the wonderfully useful and beautiful art he follows.

The ascent was made by the party November 30th, and as the "bridal path" and the "carriage road" were hidden by the snow, the railroad track was selected as the surest way to guard against being lost, which latter is no uncommon thing in mid-summer; for, as you know, it is one thing to stand at the base of a mountain, high or low, and strike a bee-line with the eye to the top, and another thing to follow that bee-line to the summit. The railroad, a photograph of which you have been made familiar with by its issue with the December (1869) No. of the *Philadelphia Photographer*, was sure to lead to the summit, and so, as long as they kept near it, they would not be lost. Mr. Clough says:—

"When we started it was clear, and warm, and pleasant, and we perspired freely. As we got up out of the woods near 'Jacob's Ladder,' a high trestle on the railroad called by that name, the complexion of things changed; dark threatening clouds stretched along the crests of the Green Mountains, and were moving down upon us in a solid mass. We made haste to reach the top. Mr. Kimball, not being used to such tramps, was getting fatigued, and had left his pack at the foot of the ladder to lighten him for the rest of the journey.

"When we had got some way upon the open ground it was sunset, and the clouds had begun to drive across the top of the mountain; in fact, it began to look serious; but after some consultation, we determined to push up, as it was further back than up, and very dangerous walking on the railroad in the night. Moreover, there was no shelter but the depot at Waumbek Water Station, and no chance to make a fire even there. There was some danger of getting lost unless we kept in sight of the railroad. We were soon in a dense cloud. Mr. Bracy got separated from the rest of us here, and Mr. Kimball declared himself 'played out.' What were we to do? Leave him to perish and save ourselves, or to make an effort to get him up? I thought I had strength to do it. I certainly had the will. Mr. Cheney declared himself ready to try, so we went around a ridge a little, out of the wind, and rested. At the same time we rubbed and slapped

our exhausted friend with the flat of our hands, which does a great deal towards restoring a person in that condition.

"After a short rest, and having dropped all traps that would load us down, he took a small cord in his hand, whilst I drew the other end over my shoulder, Cheney locked arms with him, and then we pushed up into the clouds and darkness. We had a full mile to go, and he was growing worse fast; we had to resort to rubbing and slapping, letting him drop behind anything that would break the force of the wind. He begged us to leave him, and take care of ourselves. I was excited, and could have done a great deal more as long as my strength held out, and I knew if reaction did not set in, or Mr. Cheney give out, we could get him and ourselves up safe by resting often. We at last got up the steep part to where the ground was less rugged, and snow harder, with the wind on our backs, which helped us along. Across this we made rapid progress. Then we had to turn to the right, and go up a sharp rise to the depot at the summit, which brought the wind partially in our faces. We crossed over the track here to get some protection from the wind by tressel-work. Our friend was so far gone as to move mechanically, and we were obliged to let him rest often, dropping down helpless. We would wrap our overcoats about him and gathered close about so as to impart as much warmth as possible. We soon passed the spot where Miss Bourne perished at a much earlier season of the year. Could we make the rest of the way, or would there be a second monument of rough unhewn stones erected by strangers to the memory of one who had dared to face the fierce blasts of winter? I felt my strength leaving me; the excitement had driven me beyond my usual strength. I knew it was but a short distance, but my friend Cheney still supposed we had some way to go, and he worked bravely on. We could now go but a few feet at a time. The wind was blowing in our faces, the ground rough and steep, and I was obliged to rest often, and then exert myself for one more lift. At last, we caught sight of the house but a few feet away, and if ever there was a welcome sight, this was one to us. We gained the entrance and gave a shout, but the wind was so fierce as it rushed around the corner that we were thrown down. The party inside, members of our expedition who had gone before, heard us and rushed out, and dragged our now almost wholly unconscious burden into warm and comfortable quarters. No limbs were frozen, so we received no injuries except being exhausted."

So much for the perilous ascent. Since they have been on the summit they have had several days fit to photograph, and have made a great many beautiful frost and winter views, some of which I hope to send you soon after the negatives reach mother earth. I have not space or time to even begin to describe the grandeur of the scenery from one of these white mountains in winter. Many a tough struggle have I had on snow-shoes to get such views, in company with my good friend Kilburn, of Littleton, N.H.; and as we have arranged a trip up Mount Washington in a few weeks "to see the boys, and take them the PHOTO NEWS and some papers," I may be able to tell you more after I come down to my usual level as your correspondent again.

The Use of Warm Water in Toning.—At the last meeting of the Pennsylvania Photographic Society considerable discussion was had on the use of warm water in toning solutions. We all know that warm water will accelerate toning in cold weather, but the results are not so rich or pleasing. After prints are toned, and washed and dried, however, Mr. Shoemaker, assistant to Mr. Albert Moore, whose solar enlargements you have so much praised, declared that if they appeared too blue in colour, they could be improved by steeping in boiling water. Prints shown by him verified his assertion. In printing on opal glass, if the tone be too red, it may be improved in the same way.—Truly yours,
EDWARD L. WILSON.

Philadelphia, January 16th, 1871.

TESTS FOR THE PURITY OF PHOTOGRAPHIC CHEMICALS.

No. 1.

BY PROF. J. TOWLER, M.D.*

IN the present advanced condition of photography, it becomes important for the photographer to know how to test his chemicals for impurities; for such exist, more or less, either accidentally or intentionally, in many of the chemical ingredients used in the photographic art. The aim of the present article, therefore, is to give the photographer the requisite instruction in chemistry, by means of which he can form an independent judgment as to the normal or abnormal condition of what he uses.

TEST FOR NITRATE OF SILVER.

Nitrate of silver crystallizes in plates, which are quite peculiar and easily distinguished from other almost similar crystals—as, for instance, from those of the iodide of cadmium. The crystals of nitrate of silver are very heavy. If crystals of quite a different shape from the tabular form are distinguished amongst the flat plates peculiar to nitrate of silver, there is a great probability that such crystals belong to some other substance; and by picking a few of these out by means of a pair of forceps, and submitting them to the following chemical test, you will easily be convinced of this fact.

TEST WITH HYDROCHLORIC ACID OR A SOLUBLE CHLORIDE.

This test is one of the best, for it shows the presence of silver very distinctly, and requires only one extra test, in reality, for its corroboration, but others may be added. This reagent, too, separates silver from many of its solutions completely in the form of the chloride of silver. Add, therefore, a drop or two of hydrochloric acid, or of a solution of common salt, to the solution of the supposed nitrate of silver (two or three grains of the salt in a drachm of pure water). If the salt is really that of nitrate of silver, a slightly bluish-white precipitate is produced. Such a precipitate, and one that is almost similar in colour, is produced by this reagent when it is added to a soluble lead salt (nitrate of lead, acetate of lead), as also when certain soluble chlorides are added to a solution of bichloride of mercury. It is therefore necessary to determine, by a second test, whether the precipitate in question is chloride of silver, chloride of lead, or chloride of mercury. As I said before, one single test is capable of doing this; namely, pour the liquid off from the settled precipitate, add water to the latter, shake the mixture well together, and then let the precipitate again settle to the bottom. Again pour off the supernatant liquid, and finally eject the moist precipitate into a white porcelain evaporating dish, and expose the contents for a few minutes to the direct rays of the sun. By this proceeding chloride of silver changes colour, and gradually assumes a lavender hue. Chloride of lead and chloride of mercury are not visibly affected by this treatment, as regards colour. Hence this test is decisive as to the presence of nitrate of silver; but, naturally, it does not prove that there is, or is not, either chloride of lead or chloride of mercury, either one or both, precipitated at the same time with the chloride of silver. To determine the presence of chloride of lead in the mixed chlorides, the latter are boiled in rain or distilled water, by which the chloride of lead is dissolved; the boiling-hot solution is separated from the insoluble residue by filtration or by decantation; and, on cooling, the chloride of lead again separates in brilliant crystals.

The presence of chloride of mercury is determined by adding to the two remaining chlorides a little ammonia, which easily dissolves the chloride of silver, but which turns the chloride of mercury black, or of a grey black.

Numerous other tests might be employed, but these will be found, I think, quite sufficient to determine the pre-

* Philadelphia Photographer.

sence of these three metals when combined or mixed as nitrates, and precipitated as chlorides.

But nitrate of silver is sometimes adulterated with nitrate of ammonia, which really does no injury if the salt is used simply for photographic printing on paper; but such an adulteration is an injury to the purse, and so far a fraud, because you have to pay for nitrate of ammonia the same price as for nitrate of silver.

TEST FOR NITRATE OF AMMONIA MIXED WITH NITRATE OF SILVER.

Take a few grains of nitrate of silver, and rub this salt intimately together in a mortar, with a little quicklime and a drop or two of water; if there is any ammoniacal salt present, the smell of ammonia will at once be evolved by this operation.

In order to ascertain the amount of nitrate of ammonia present, we proceed in the following manner:—Weigh out, for instance, twenty grains of the salt in question, and heat it by means of a spirit-lamp in a porcelain crucible (or weigh the crucible and the salt together); then, as soon as the salt melts, white fumes will be evolved, if there is any adulteration with nitrate of ammonia. Continue the heat gently, until no more white fumes pass off, let the crucible cool completely, and then finally again weigh the crucible and its contents; the difference in the two weights determines the amount of the nitrate of ammonia which had been mixed with the nitrate of silver.

But it may be that either the nitrate of soda or the nitrate of potassa may be the adulterating ingredient; and as neither substance is volatilized by heat, we have to show their presence and effect their separation in another way. Now we know that neither of these salts is precipitated by hydrochloric acid; therefore, add hydrochloric acid to a solution of the nitrate of silver under consideration as long as a white precipitate is thereby produced; afterwards separate the liquid portion from the deposit by filtration. This liquid portion contains the adulterating ingredient, be it either nitrate of soda or nitrate of potassa. Now evaporate the fluid to dryness, and divide the residue, if there is any, into two parts. Dissolve one part in a very small quantity of water, and divide the solution into two parts. To one of these add a drop or two of an alcoholic solution of bichloride of platinum, which will produce a yellow crystalline precipitate of the double chloride of platinum and potassium, if the substance in the solution is nitrate of potassa. Add to the other part of the solution a few drops of an alcoholic solution of carbazotic acid, which will produce, also, a yellow crystalline precipitate if a salt of potassa is present. These two reactions will fail if the adulterating material is a salt of soda.

Furthermore, we may test for the presence of a soda salt by using the portion of the dried deposit and placing it on a piece of burning charcoal; if soda is present, and especially the nitrate of soda, the salt will evolve a bright yellow flame, and decrepitate. If, however, the salt were pure nitrate of potassa, the flame would be of a light purple or rose colour.

Again, let us suppose that no deposit was left after evaporating the fluid—originally obtained by filtration—to dryness; this circumstance would indicate, if ammonia had already been tested for and found wanting, that the nitrate of silver under examination was pure from all metallic or basic compounds.

To test the solution of the nitrate of silver in question for any free acid, which ought not to be present, we use blue litmus paper, which turns red; if the colour is not changed, there is no free acid. If, however, the colour is changed to red, test for sulphuric acid by adding a drop or two of the solution of chloride of baryta to the solution of nitrate of silver; and if a milkiness is produced, this indicates that sulphuric acid is present, and this indication is strengthened if, on addition of nitric acid, the milkiness still remains.

More probably nitric acid may be present, and this, in very small quantity, will scarcely be injurious.

Many other substances might be present, but there is not much probability of finding anything besides what we have tested for.

ALKALINE DEVELOPMENT.

BY M. CAREY LEA.*

I RETURN to this subject to mention what I find to be a convenient and advantageous mode of managing it.

Before commencing to develop a set of plates, put into a small phial

80-gr. solution of carb. am....	...	3 drachms
60-gr. solution of bromide pot.	...	1 drachm

Shake these well together.

Next place (for a $6\frac{1}{2}$ by $8\frac{1}{2}$ plate) 4 ounces of water in a pan that will just take the brass plate. Add to this half a drachm of 60-grain solution of pyrogallie acid, agitate to mix, and put in the plate, which will simply need to have the backing sponged off, but not to have had the face washed.

The liquid moistens the plate all over, but does not develop anything (usually not, unless the exposure was too great, or the pyrogallie acid has traces of ammonia in it from being measured in the same minim glass as the alkaline mixture without intermediate washing). Now remove the plate, and add to the pyrogallie acid and water 20 minims of the mixture of carbonate and bromide; agitate, and put in the plate. The sky at once appears, and presently the details (in the case of collodio bromide plates, prepared as I have described; these come as rapidly as in wet plate development). Just as soon as the details are out, the plate is again taken out, and about 25 minims of the carbonate of ammonia solution, without the bromide, are added. This completes the development.

Always, however, the operator watches the character that his plates show. If there is a faint disposition to veil, the bromide should be increased. Any desired degree of brilliancy is got in this way, up to the most brilliant ambrotype effects. This last, however, is undesirable, and tends to the production of hard prints.

THE SOLAR ECLIPSE IN SICILY.

BY DR. H. VOGEL.†

THE English Government had placed at the disposal of the expedition a despatch boat, the "Psyche," a small, but swift and pretty vessel, which, on the afternoon of the 11th December, left the beautiful Bay of Naples, and reached, the next morning, the Faro of Messina. The pleasure of the trip along the coast of Sicily to Catania was much enhanced by fine weather, and was certainly one of the most enjoyable trips I have had in all my wanderings. Chains of hills run from point to point, each of them a landmark of some past glory; the blue Mediterranean, the picturesque cliffs, the giant Etna, towering above all, with its pyramidal snowy sides and smoking crater, compose, with human monuments of the past and present, a picture which must impress even the most stolid. It was in the midst of this beautiful scene that an unexpected calamity befel us: our vessel struck upon a submarine rock, some seven miles north of Catania, near Cape Mullini. Fortunately, we were all saved, with our luggage and apparatus, and were enabled to reach Catania in a boat the same day.

Here we met the American expedition. The staff—not so numerous as ours—had already found quarters in the gardens of a beautiful Benedictine monastery, where they had fitted up their observatory, and where we, in passing, gathered oranges from the trees. Here I found my old

* Philadelphia Photographer.
† Continued from p. 53.

friend Mr. Chapman, Professor Rutherford's assistant, with whom I had become acquainted in New York. He, together with Mr. Burgess and Mr. Fitz, of New York, formed the American photographic section, which was provided with a magnificent telescope having a six-inch aperture, and some beautiful landscape lenses. We were told, at this station, that the Italians had sent a photographic staff to Angusta, and these circumstances determined Lockyer to send Messrs. Brothers and Fry to Syracuse, while six other observers—of whom I was one—were to choose a more northern locality.

My first idea was to station myself upon a spot in the central line, where the eclipse would last longest; and here, with the aid of a heliostat, kindly lent to me by Professor Pogendorf, and an ordinary camera with a sliding dark-box arrangement, to obtain three pictures of the corona, one after the other. I could quite rely upon the possibility of such a course of proceeding. In Kentucky, on the 7th August, 1869, a picture of the corona was obtained in forty seconds with a telescope of $\frac{1}{15}$ * aperture; my lens was $\frac{1}{2}$ in relation to the aperture, and the light intensity of this, compared to that of the American instrument, would be $(\frac{1}{2})^2 : (\frac{1}{15})^2$, or nearly in the comparison of 1 : 4 $\frac{1}{2}$. With my instrument, therefore, I could work four and a-half times as quickly, and produce a picture in nine seconds. But it must be remembered that the mirror of my heliostat, which reflects the picture of the sun upon the lens of the camera, would absorb fifty per cent. of the light, and for this reason it would appear necessary that an exposure of twice the above period would be necessary. Under any circumstances, then, it would be possible to obtain three or four pictures during the one minute and a-half of totality with the facilities at my disposal. In obtaining pictures in this way, one after another, I was, moreover, anxious to confirm Gould's observations in America, which seemed to demonstrate the fact that the corona underwent some very striking and rapid modifications. I was likewise desirous of obtaining a picture of the corona through a piece of kalspar, in order to ascertain, by means of the double picture, whether the light of the corona was polarized or not.

Lockyer's wishes, however, altered my plans. In order to ascertain whether the corona was of atmospheric origin, it was of great importance to him to have observations of the same made at one spot situated a considerable distance above the level of the sea, for at such a point it is evident the atmospheric influence would be much less than at a lower station. The mountain of Etna, 10,200 feet in height, offered a favourable observatory of this kind; and for this reason a portion of the staff was despatched to Mount Etna, with orders to establish themselves as high up that mountain as circumstances would permit. Of this division I formed one, and was, indeed, the only photographer of the party. On the first days of our setting out, the weather appeared very promising. The purest spring atmosphere and a clear sky gave us a splendid view of the mountain, and raised our hopes to a high pitch. Of course the period of totality (about one minute) would be scarcely so favourable for my work, but then I trusted, on the other hand, that the clearness of the atmosphere would allow of a much shorter exposure.

On the 21st December—the day before the eclipse—we parted from our friends at Nicolosi, at the foot of Mount Etna, and commenced our ascent. Two American observers, Messrs. Peters and Einbeck (both of them Germans), accompanied us, and took up their station near the small crater of Monte Rosso, at a height of 2,550 feet. We entrusted our packages to a team of mules, and ascended in a long cavalcade. The path led over volcanic ashes, and then across the lava stream of 1573, whose irregular surface assumed all kinds of fantastic shapes in convincing the eyes, however, less than the feet. Numberless minor craters were to be seen on all sides, covering

almost the whole side of the mountain; they are said to be 800 in number. These craters have been quenched for some considerable time, and the surface of many of them, both outside and in, is covered with good arable land. From the very summit of the mountain evidence of subterranean fire was continually to be seen, sometimes a white and sometimes a grey vapour being discernible issuing from the crater. As we ascended, the cold became very perceptible. The thermometer sunk from 11 $\frac{1}{2}$ ° Reaumur to 8 $\frac{1}{2}$ ° on the further side of the lava stream, and finally to 5 $\frac{1}{2}$ ° at the Casa Ferentina, our destined goal.

(To be continued.)

Correspondence.

DEVELOPING TRAY.

DEAR SIR,—Having constructed a developing glass tray, I enclose you two drawings of it, which will, I think, serve as an answer to the enquiry of "Oxonensis" in a recent impression.

The frame, or sides of the tray, are of mahogany, about 1 $\frac{1}{2}$ inch deep, slanting down to about 1 inch to the right-hand side.

Fig. 1. represents a general view of the tray; A, the

Fig. 1.

plate-glass bottom, fitted into a rabbet in the wood with white lead, so as to leave a quarter of an inch between the glass and the table on which it stands. B represents one of the two pieces of mahogany (seen better in the bird's-eye view given in fig. 2 at B B), an inch in width, fitted to the inside

Fig. 2.

of the frame on the glass. These pieces are about twice the thickness of the collodion plate, and serve to form an inside tray one-eighth of an inch larger on every side than the plate itself. C represents the corner a little cut out to admit the finger-nail to lift up the plate. Shellac varnish covers the inside woodwork.

In this arrangement my aim has been to form a tray in which to develop a plate with the *smallest* possible quantity of solution, so as not to weaken the image. In use, you have only to tilt the tray towards the left hand, and slide the plate immediately into it.

The pieces of mahogany let in also serve to secure the developer without pouring it away when tilted up to watch the progress of the picture.

* Viz., comparison of aperture to focus.

If this communication should prove of any service to your correspondent or others, I shall be only too glad.—I remain, dear sir, yours faithfully,
JOHN B. BEST.

KEEPING SENSITIZED PAPER.

SIR,—I have tried the "washed paper and fuming process," and my experience is, that as regards the production of fine prints it is perfectly satisfactory; but still, as is not unusual in many other good things, it has its drawback—at any rate in my case. On account of my printing arrangements, I find it a very troublesome affair, with a large number of negatives, to fume the pads.

I have not used any of Mr. Darand's paper, which, he states, will keep two months, and may be used without fuming; but an amateur friend of mine reports very favourably of it, and I cannot but very much wish that some process was known by which photographers could sensitize their own paper with these advantages. I have no wish to deprive Mr. Durand of any advantage he may derive from keeping his process secret. No doubt he spent time and money in experiment, and he has a perfect right to endeavour to reimburse himself in any legitimate way he thinks proper. But, besides the desire which every photographer who takes an interest in his art has in knowing all about the materials he is using, it is rather troublesome to be constantly watching your stock of paper, so as to order it and not have any in hand more than two months. It would, therefore, be a most desirable thing that it should be generally known how to sensitize paper, and to keep it (if but a few weeks), and to work well without fuming.

My motive in writing this communication is to endeavour to prompt some of your experimental correspondents to give their attention to the matter, and, if successful, to be generous enough to make the means by which they have succeeded known.

As soon as we have a little better printing weather, I intend to try some experiments, and, should I succeed, I shall be delighted to publish the means. I am only afraid that my limited chemical knowledge may be a hindrance to me, but I shall try my best.—I am, sir, your obedient servant,
M.

January 28th, 1871.

PHOTOGRAPHY AND ITS RELATIONS TO THE STATE.

DEAR SIR,—By a misprint, the word *organization* has been substituted for *centralization* in the paragraph in my paper commencing "The French error of excessive centralization."

As both that and the succeeding paragraph relate wholly to errors of centralization, and not of organization, they are open in their turn to be charged with the logical error of inconsequence.—I am, dear sir,
S. THOMPSON.

10, Cathcart Road, S.W.

CLEANING OFF VARNISHED NEGATIVES.

DEAR SIR,—Perhaps the following, or some part of it, may be of use to a few of your readers, especially those of them who do small-sized pictures. It relates to the cleaning of varnished negatives, and preparing them for use again:—

In 1869, having no time on hand, any old negatives lying past me were destroyed; but this winter I bought a fish pan that holds about nine pints, which was filled with the plates set on edge round about, and touching each other as little as possible; these were covered with water, and about two ounces of black ash put into it; the pan was set over the fire at a convenient time, and allowed to boil for half an hour or so; was then set aside to cool; emptied; and filled and emptied again several times with water from the pump; the glass was then wiped with a coarse cloth, and left to drain; then rubbed up a little on both sides with a clean cloth, and put past. The white of an egg was put into a bottle with a few ounces of water and some pieces of broken

crookery; was well shaken; then put into a twenty-two ounce bottle filled with water, and filtered, after having been well shaken again, as advised by a correspondent in December last. Part of this was then poured into a bowl, and a broad brush was used to coat the plate with, which was then left on a plate-rack to dry. (The brush was used by me some time before I knew that another correspondent had been using one; but this, of course, is of no consequence). Any experience I have had since is all in favour of coating with albumen, and putting it on with the brush.

I have tried Tunicare for new glass, but could not get the acid put on without other matter being left along with it; and it was not convenient for me to lift the glass out of acidulated water immediately before applying it. W. C.

CARBON PRINTING V. SILVER PRINTING.

DEAR SIR,—Happily, in easement of the task now before me, the courteous letter of Mr. Cooper can be disposed of in the one remark, that his well-meant suggestion would prove more troublesome in its execution than satisfactory in the results realized. My friend "X. Y. Z" who quotes Sheridan Knowles, and selects a *nom de plume* from the unknown, must not, however, be so summarily dismissed.

The sophistry which imparts a sparkling, though false, glitter to the line of argument adopted by my friend, who prefers to shout under cover, is so thin and transparent that I think I do him justice in expressing my belief that he is ruled by a misconception of the subjects on which he so brilliantly comments, rather than a premeditated desire to bolster up a weak case with personalities and viciously conceived insinuations. Most certain is it that his remarks concerning the Heliotype process go to prove that he is not conversant with its principles or its working details. Although Edwards's Heliotype is somewhat analogous to lithography proper, it does not necessarily follow that the analogy extends through all its details. In point of fact, it does not so extend, as I am prepared to show. In the first place, a lithographic impression is produced by a rolling-press that scrapes the stone as the rollers revolve. Heliotype requires vertical pressure. An ordinary lithograph is engrained, transparency of details being produced by the breaking up of parts into irregular markings, which, I believe, is technically termed "grain." Now, in an Heliotype from nature, there is literally *no grain*; the tones glide as imperceptibly as those seen in a silver or Autotype print taken from the same negative. The present weakness in the Heliotype is not a lack of depth or vigour, but it consists of a want of transparency, without which there can be no richness. This failing, however, is not occasioned by a defect inherent to the process, but it arises from the defective practice of producing pictures by a misapplication of colours. That it is as I state I hope one day to prove: at present I have no leisure to devote to the experiment.

"X. Y. Z.'s" remarks on teapots and cruet-stands I regard as inapplicable to the subject under discussion, as it is an error too absurd to suppose that those influences which tarnish silver plate are as capable of destroying silver prints, as the chemical conditions the two present are by no means to be classed as analogous. Dozens of the readers of these lines could, if they choose, produce evidences of the lasting qualities of silver prints. Could silversmiths subscribe to similar experience with their wares? Fact of the matter is, the fading of a silver print is a *possibility*, not a *necessity*, and I have already shown that a silver print will not fade (if the past is admitted as a criterion) except decomposition is set up in some stage of its production. I deplore the ease with which destructibility can be introduced as deeply as any one can do; but I am persuaded that until some process giving equal brilliancy to silver can be brought forward, the general public, who look to present results, will choose silver prints in preference to the inferior appearances of any superseding process. In my admiration of Woodburytype, my absurdity is not so evident as the *unknown* asserts, as the

character of Woodburytype and Autotype is not "absolutely identical," the point of divergence being, in my opinion, one of notable importance. A Woodburytype picture is composed of gelatine and colouring pigments—nothing more; whilst an Autotype embodies in its structure gelatine, pigment, and chromic acid, the last being in chemical union with the first named, forming a combination which time has yet to pronounce permanent. Granting, however, the lasting quality, the chromic acid will always prove a barrier to the perfecting of the process. All who are conversant with the property of colours are aware of the difficulty of killing out a chromic yellow: with black it gives a dusky green; with red, from blackdust to an orange; with blue, a decided green; hence the causes why the products of Woodbury's invention outrival those of Autotype in brilliancy. Even were both in qualities equal, the rapidity of production of Woodburytype stands unsurpassed; therefore, taking rapidity of production and superiority of results as criterions, I am not so very absurd in my admiration of the process.

As "X. Y. Z." commences with a quotation, I shall dismiss him with an appeal to his better judgment to determine whether, in the event of his continuing his part in the contest, it would not be advisable for him to deal with facts rather than to run impulsively into personalities, which only tend to wound a sensitive nature, but constitute no more formidable weapon.

Now, sir, I turn towards yourself. You, at least, know how to deal with argument with a courteous bearing. I therefore may, with confidence, request of you a word or two of explanation.

You state, first, that no charge is made for permission to work the Autotype. Second, that an improver would be quite at liberty to use his improvements—I presume, without charge. But how do you reconcile these assertions with the advertisements of the Autotype Company, which warn, while they assert the superiority of the pigmented tissue they supply? Now, if to use the "dearer and inferior article" renders the user liable to legal proceedings, I cannot perceive how the improver of a tissue can be safe in using his improvement without paying in some way for the privilege.

[Surely it requires no argument to show that whilst it is illegal to make without permission the article which someone has invented and patented, it may be perfectly legal to invent a better. If the real or supposed improvement involve the use of the patented method as a basis, of course that must be paid for; but if the improvement be of a radical character, and dispense with the original patent altogether, the inventor is free as air to patent for his own benefit, or keep secret and use for his own benefit, or publish and give to the world.—Ed.]

Perhaps your reading of patent law forms the basement of your remarks. Most certainly it has enlightened my mind in reference to the Christian forbearance exercised by the patent holders, when the legal protective rights of Autotype are violated.

But I must not dwell on this matter, as there remain to be disposed of the remarks of industrious Mr. Johnson, to whom I should consider myself deeply indebted for the pains he has taken to prove that I have never shrunk from showing up the weak points of the process I am now defending. So high is his opinion of my honesty in this respect, that he foreshadows a period when I may be introduced as an authority that proves the instability of silver prints. But I am withheld from an expression of obligation by his suspicious omission of an explanation which should be added to prove honesty of purpose. My confession of weakness is always accompanied with an explanation of the course to follow to avoid such weak places. Besides, what Mr. Johnson admires in theory he would do well to imitate in practice. He is always harping upon the strong points of Autotype. Has the process no weak points? I could name and describe a few.

Mr. Johnson deserves, and I freely concede to him the credit due to him on account of the moral courage and laudable candour evidenced in his unreserved confession in reference to those, his clients, "who practise the carbon process habitually, who use the fact extensively, but quietly and most successfully, to attract clients, and disparage the silver prints of their neighbours, but who also, with equal perseverance, decry the process to enquiring friends." Equal upon such a miserably selfish and meanly conceived policy—unworthily the proceeding of men, insulting to the liberal antecedents of an art whose deepest foundation is grounded on a rock of unselfishness! I have not yet reached that stage of cynicism which would induce the belief that photographers are so steeped in the degradation of lying and hypocrisy as to hug in secret what they openly decry. Mr. Johnson believes in the possibility of my having found a "mare's nest." Is he certain that he is not the deceived? In my case my eyes were permitted to endorse the evidence received by my ears; but it might reasonably be suspected that Mr. Johnson's ears were the only recipients of the testimony of his cellar-groping clients; for those who openly decry would scarce trust him with secrets they desired to keep close from the outer world. The Autotype Company, I presume, do not advertise their wares from motives of philanthropy. They plainly desire an extension of a consuming connection. Is it at all reasonable, then, to suppose that those disparagers of a process would accord praises in the hearing of an active principal whose interests it would be to proclaim aloud such praises by mouth, pen, and press? If Mr. Johnson has not been deceived, his dubiously reticent clients are certainly much more foolish than even dishonest.

Concerning Mr. Johnson's challenge, I would honestly and at once accept the same, but can I depend on the absence of Mr. J.'s cellar friends from the list of triers? Surely

"Since man to man is so unjust,
How know I which man I may trust?"

If there exist those who practise habitually what they decry openly, what guarantees have I that the elasticity of the jury conscience might not extend to lauding openly what they decry in secret? Ah me! this is a wicked world. And the more I try to draw some scheme to obtain a free and fair trial, the greater becomes my bewilderment. Stay! Is it too long to wait? The next exhibition—they cannot pack the opinions of viewers there; for I fearlessly state my conviction that I could expect no impartial verdict from the photographic press. It would, doubtless, strive hard to be just, but a foregone conclusion is like unbridled prejudice—it is hard to combat it. The correctness of this statement is shown by the fact that the query embodied in the position has not yet been answered straightforwardly: "Can Autotype honestly assume the power of meeting all the requirements, which powers photographers are at no loss to find in silver printing?"—Yours truly, W. T. BOVEY.

[Regarding the challenge, Mr. Bovey overlooks the fact that Mr. Johnson stipulates for publicity in the form of a few friends selected by both sides; the facts reported upon—by the press, of course; and the results exhibited.—Ed.]

HELIOTYPE PRINTING.

SIR,—I greatly hesitate to make any remarks on the subject of heliotype printing, feeling that such remark cannot, of necessity, be considered impartial; but I may^s at least, correct some obvious misstatements which your correspondent "X. Y. Z." has made in relation thereto.

Your correspondent states that the heliotype process, in its mode of working, is strictly analogous to lithography. But, beyond the fact that lithography entirely, and heliotype partly, depend for their principle on the mutual repulsion of grease and water, the modes of working are altogether dissimilar. In lithography, a drawing composed solely of dots or lines is made on a stone, and the only effect of gradation that can be produced is by making these dots or

lines larger or smaller. There can be no difference in intensity, only in size, between the largest and the smallest. In heliotype, the image is produced by the action of light passing through a negative on to a sheet of gelatine. The surface of the stone is as coarse, compared with the gelatine, as is a newly macadamized road compared with the first-named surface. In the one case the image is produced by what degree of fineness of dot or line the hand may be able to attain; in the other, by the degree of fineness that light will produce through a negative on the surface of gelatine. It may be replied that it is only a question of degree. Obviously it is, and must be so in all printing methods, either in tin, or silver, or carbon. But the degree obtained in the heliotype is such that it is impossible to separate the gradation into dots or lines, even with a powerful magnifying glass.

The device of double inking affords another illustration of the total dissimilarity in the working of the two methods.

In the heliotype it is found that a stiff ink will only adhere to those parts where light has acted most strongly, and in order that it may adhere where the action of light has been less, it must be thinned down. This gives heliotype a very distinct advantage over lithography—and, indeed, over all existing methods of printing—where no such effect is obtainable. I have remarked that in heliotypic printing, the action is only *partly* that of the mutual repulsion of grease and water, for its mole of work is also *partly* that of copper-plate printing; there is a distinct amount of relief in the gelatine surface from which the impression is made, and, in the case of lines, a perceptible amount of relief is obtainable in the prints.

Your correspondent says of heliotype, that it cannot rise higher than the best lithography. Let him consult any lithographer, and he will find he is in error in this respect.

It would be out of place for me to remark on the comparisons of results which your correspondent has made. These must, after all, be purely matters of individual opinion, and I am content to refer to the published opinions of recognized authorities on this point.

It is at your pleasure to give your readers the opportunity of judging of the merits of heliotype for themselves.

Some time since I placed an illustration at your disposal for this purpose, the subject of it being an interior. You were of opinion that a figure piece would be better, for which you were good enough to say you would find the negative. To that opinion I deferred, and am awaiting instructions.*

I suspect the want of permanence is not the only objection, nor, indeed, the greatest, to the commercial application of silver printing. The necessity for mounting, the cost, the want of uniformity in the results, the limited range—above all, the time required for the execution of any extended number of copies, and the helplessness of the method, from its dependence on light—these are the obstacles which, more than want of permanence, have entirely barred its progress. Portraiture is said to be the crucial test of a process, but it can only be so as regards portraits. A publisher of reproductions or engravings, for instance, would not consider it a test for his work. Outside the domain of portraiture, there is an enormous field for a method which obviates the objections referred to, and the method will assuredly be preferred, *ceteris paribus*, which supplies a print in printing ink, to that which supplies one composed of colouring matter imprisoned in gelatine.

The want of uniformity in quality in silver or carbon printing is so serious that, in my opinion, 1,000 or 500 impressions by either of these methods would not, *as a whole*, be so good as a similar number of heliotypes from the same negative; this is putting on one side the advantages in point of permanence, time, mounting, range of power, and

* We preferred a figure subject as doing more justice to the process, and of more interest to our readers. We hope to issue it with an early number.—Ed.

cost that accrue to the heliotype, though it may be that, *at present*, selected prints by the first-named method might prove best of all. In this extended sense I agree with Mr. Bovey's remark.

Silver printing is a thing of itself. It stands entirely alone, and produces results unlike everything else. It has been in existence a score or so of years, and has had thousands of workers. It is, in fact, the established process. People, from being accustomed to it, like it, though it has but few points which find favour with artists. But what I object to, and what carbon printers have to fight against, is, the settled conviction that a silver print is to be esteemed the standard of excellence. No matter how much more artistic the results, no matter how great the range of a new method may be, no matter how permanent, or how quickly or cheaply manufactured, no matter what other advantages it possesses, the one point always is, can it produce pictures that shall be mistaken for silver prints from the same negative? If not, *Habet*, and down with the thumbs. If autotype or heliotype printing, even with only their present excellence, had been the established methods, and silver printing had now first been brought forward, what would have been the chance of its introduction?

There is, just now, a general cry about the depression that exists in photography. And yet there is a class of men springing up who find their account in being simply autotypers, Woodburytypers, heliotypers, carbon printers, &c. I venture to predict it will not be long before photographers suddenly awake to the fact that more work is being done by photography now than ever, but that it has unaccountably slipped into new channels.

In conclusion, your correspondent "X. Y. Z." remarks that, at the recent exhibition in Conduit Street, carbon printing was very imperfectly represented, whilst the heliotype process was exceedingly well represented. Nothing could serve my present purpose better. After an existence of six years, carbon printing was very imperfectly represented by the productions of five firms, Messrs. Sarony, Spence, Downey, Window, and Edwards and Kidd, the names of the first four being towers of photographic strength. Heliotype was, I am pleased to see, exceedingly well represented by the productions of one firm after an existence of a few months. I can afford to overlook my strongest argument, which applies with ten times the force you have applied it to carbon printing: no final comparison can as yet, with the least fairness, be made between the results produced by this and the older methods. Nevertheless, heliotype, the youngest born of the processes, and barely able to speak for itself, has made its voice heard in an unmistakable manner.—Faithfully yours, ERNEST EDWARDS.

Lincoln Terrace, Willesden Lane, January 6th, 1871.

DISSOLVING VIEWS WITH ONE LANTERN.

DEAR SIR,—If "Sylvester" will please to read the last sentence of his article of the 6th January, he will see that all of whom he was writing are included without exception in his sweeping denunciations against untruthfulness. Perceiving his mistake, he has hastened to rectify it. This is as it should be; but, as many persons are apt to do when they find they are in the wrong, and are, on that account, angry with themselves, he has pitched into the first person at hand, which happened to be me, just to gratify his spleen and let off the steam. Well, it does not hurt me, and it does not improve his position. If he is the "Sylvester" I have heard of, he has considerable scientific acquirements, but his nervous excitement has prevented his seeing that we were both working for the same ends, only from different standpoints. Seriously speaking, such sweeping denunciations should never be used; they betray an uncharitable mind, are often misjudged and unjust, do no good, engender mistrust of the motives of the writer, form no arguments upon the matter in dispute, and, worse still, prevent sensitive minds from offering their ideas and ex-

periments to the public. Ill-natured personal abuse and ridicule are still worse, as those who would feel wounded by it have not the power or the will to return it, therefore are not on fair terms with their adversary. No man has a right to say that a thing either has not or cannot be done because he has not seen it or cannot do it; for instance, my gas blowpipes, made by Field, of Birmingham, have a sliding action like a telescopic gas-burner, serving to adjust them to condensers of various diameters. Binocular lanterns having the lenses arranged one set above the other have long been in use; what, then, more easy than by rack work to raise or lower the light from one to the other of them? This is not dissolving, says "Sylvester;" so also say I; many so-called methods of dissolving are not, in fact.

The great optical error lies in this, that so far as the light is removed from the centre of illumination of the condensers, a dark patch covers a proportionate amount of the screen; and this I should consider fatal to the whole effect, and not to be remedied. Nevertheless, I should be far from vilifying the inventor, but would civilly ask him for further explanations. By the former course I might perhaps deprive myself of some useful information, and unnecessarily make an enemy.

As to my transparent error, if it be an error, it was intended to be somewhat transparent. I have always found, in a mixed audience, some turbulent spirit take advantage of the darkness to become offensive, and respectable females object to being placed in such a situation: the passing of a piece of deep blue glass over the lantern nozzle produces a night effect upon the picture. Should total darkness be required, the colour can be deepened to any extent towards the handle by oil paint. Black glass can be obtained, if preferred. Craps can be used in the manner recommended by "A Practical Man" some time since in the PHOTOGRAPHIC NEWS. I consider the best method is to have an instrument made in the shape of a musical tuning-fork, the space between the legs of which is of sufficient width to allow the lantern nozzle to pass between them. The craps is sewn on the by holes bored on their faces. I disapprove of all springs, hooks, or other attachments to the lanterns in any way, as they are likely to prove sources of danger and accident.

In conclusion, I beg to say that I consider an educational journal like the PHOTOGRAPHIC NEWS an unfit arena for personal abuse or party spirit. Each contributor should be encouraged to add his mite of instruction to the common stock; and should it prove stale or unprofitable, it should be received with charity. Our worthy Editor has the interests of his readers too much at heart to admit much such as this, but Jove sometimes nods, instances of which I frequently see in other journals. I have no doubt but that in the foregoing remarks will be found some amusing coincidences. I make no personal application of them to anyone, but merely "Noni soit qui mal y pense."—Yours truly,

106, High Street, Ilfracombe.

J. MARTIN.

Talk in the Studio.

VISITING CARD PHOTOGRAPHS.—Mr. F. A. Bridge, referring to our description of a visiting card portrait with turned down corner, sends us an example of a similar thing which he has been producing for the last four years. In this case, the corner of the card is cut off, and a triangular piece of an ordinary print pasted on instead of the medallion we described.

SENSITIVE CARBON TISSUE.—In a note speaking of the satisfactory working of carbon printing in the photographic department of the Royal Arsenal, Mr. Baden Pritchard states that they are now using carbon tissue which has been kept five weeks in a sensitive condition with scarcely any perceptible deterioration.

LONDON INTERNATIONAL EXHIBITION, 1871.—Photographers should remember that the 21st instant is the date for sending in their contributions to the exhibition. The buildings in

which this will be held are now finished, and ready to receive the exhibits. They will accommodate altogether 50,000 persons. The object of the commissioners in holding the exhibition may be summed up as follows:—They propose, in the first place, to make an international exhibition a permanent institution of the country, giving to industrial art the same opportunity that is afforded to fine art by the annual exhibitions of the Royal Academy. In the second place, they produce the area over which the exhibition shall spread itself, by reducing the various industries into groups, and, taking certain of these each year, bring the entire industry of the country under review every seven or eight years, fine art being a standing division of the programme. And, in the third place, to restrict the conditions under which exhibits have hitherto been received, by making all articles undergo a preliminary sifting, through appointed committees of selection, thus excluding all works that do not possess sufficient artistic merit to warrant their exhibition, and by the further exclusion of mere masses of natural products. The manufactures exhibited this year will be woollens and pottery, in addition to fine art of every description. H.R.H. the Prince of Wales is the President of Her Majesty's Commissioners for the Exhibition; Messrs. Spiers and Pond are to be the refreshment contractors; Messrs. Chaplin and Horne the carriers; and Her Majesty's Commissioners have entered into arrangements for the printing and publication of the official catalogues by Messrs. J. M. Johnson and Sons, of Castle Street, Holborn, London.

THE COLOURS OF AUTUMNAL FOLIAGE.—Mr. H. C. Sorby has a valuable paper on this subject in the January number of the *Quarterly Journal of Science*. The chemical substances which give rise to the varying tints of autumn he divides into five classes or genera:—1. *Chlorophyll*, or the green colouring matter, which is very rarely found pure even in fresh leaves. It is insoluble in water, but soluble in alcohol or bisulphide of carbon, and the spectrum has a well marked absorption-band in the red. 2. *Xanthophyll*, or the yellow colouring matter. This is insoluble in water, but soluble in alcohol and bisulphide of carbon. The spectrum shows absorption at the blue end. It is found in various fruits, flowers, and roots. 3. *Erythrophyll*, or the red colouring matter. There is strong absorption in the green part of the spectrum. The various kinds are usually soluble in water and dilute alcohol, but not in bisulphide of carbon. It is found in red flowers and leaves. 4. *Chrysophyll*, or the golden-yellow colours, soluble in water and dilute alcohol, but insoluble in bisulphide of carbon. 5. *Phaiophyll*, or the group of various browns: soluble in water, but not in bisulphide of carbon. These are mostly due to the oxidation of chrysophyll. Unfaded green leaves are coloured mainly by chlorophyll, but the tint is very much modified by xanthophyll, and by colours of the chrysophyll group. The various tints of autumnal foliage are produced by combinations of different members of the above groups, and Mr. Sorby gives the following scheme of their relative abundance:—During complete vitality and growth, we have different kinds of chlorophyll and chrysophyll producing more or less bright green. During low vitality and change, erythrophyll and xanthophyll make their appearance, producing more or less green-brown, red-scarlet, or bright orange-brown; while during death and decomposition, phaiophyll and humus (brown-black) usurp their places, and gradually cause a uniform dull brown colour.—*Academy*.

To Correspondents.

SILVER STAINS.—Stains caused by nitrate of silver on an absorbent body like plaster or cement will not be easy to remove, from the difficulty of perfectly washing the silver away when it has been made soluble. First apply tincture of iodine, and then follow with cyanide solution. Afterwards rinse well by means of a sponge, repeatedly applied with clean water, and then squeezed out.

JAMES HAYWARD.—The transferred collodion print you enclose is very much over-exposed and over-developed, and hence it is fogged. If you had stated the formulae and details of its production, we could have pointed out more specifically the remedy. Expose a shorter time; use a weaker developer with more acid; and develop a much shorter time. 2. Photography has, for some months during this winter, been almost at a standstill in London. We never remember a more unfavourable season for the practice of the art.

R. L.—A solution of Schlippe's salt will give a bright red tone to transparencies. You will find details in our volume for 1865, or in our YEAR-BOOK for 1866.

ARTHUR THOMPSON.—The prints should be kept from direct contact with zinc whilst washing. Let your washing trough be well varnished, not painted. Shellac varnish, or a varnish made of collodion and boiled linseed oil, will answer well. 2. The mere use of running water does not secure the most perfect washing. To secure certainty, it is desirable that two or three times during the washing the prints should be lifted out of the washing water singly, and allowed to drain thoroughly, and then put into clean water. This, combined with a few hours running water, will be found very efficient.

D. D. (Belgian Subscriber).—The quick-acting single stereoscopic lens is not so rapid as the No. 1 B of the same maker. The last mentioned is the best for all the purposes you name. The description of Mr. Blanchard's developing box appeared in the PHOTOGRAPHIC NEWS, September 25th, 1863, and another description of an improvement therein, July 16th, 1864; but as these numbers are out of print, we regret that we do not know of any mode of procuring them. Mr. C. E. Elliott manufactures the box for sale.

W. J. A. G.—For the length of your studio we do not recommend more than 28 feet, and for width 12 feet or 14 feet; we should prefer 12 to 14 feet. Too large a studio has many disadvantages. The pent-house, or lean-to, form is good, like that in your diagram No. 2. If the height be 14 feet at south wall, and 7 feet at the eaves, you will get a convenient angle for every purpose. Let about 6 feet be opaque at each end, both side and roof, and inside allow the glass to come within about 26 inches of the ground. By having a portion of the top flat, you would gain nothing, and would lose some light. In such a studio as that now contemplated, you will have very little difficulty in securing capital effects of lighting. By working cross-cornerwise of the room, quartering the sitters towards the light, you will have plenty of light on both sides of the face without any south side light. The blinds in such a room may be very easily arranged.

F. WHIGLEY.—The manufacture of papyroxylene by Dr. Liesegang's method involves more trouble for an amateur than the ordinary method of making pyroxylene with hot acids, and success in the first mentioned method depends upon experience. To all appearance, the sample you enclose is pretty good, and, in burning, seems to possess desirable qualities. Actual photographic test alone could determine with certainty, however. The paper is somewhat finer than that used by Dr. Liesegang. For amateur work we should recommend the use of hot acids. If you use equal proportions of nitric acid at 1-420, and sulphuric acid at 1-840, a temperature of from 140° to 150° Fahrenheit for cotton, and of about 130° for paper, will give good results.

II. Y. J.—The dimensions of your proposed studio are somewhat small, but if you cannot secure a larger room the proportions are pretty good. We should, however, prefer a little greater height at the ridge, or a few inches lower at the eaves, to secure a better pitch for the roof. The former would be better. 2. White is the best colour for blinds under ordinary circumstances. 3. A studio of these proportions would scarcely give scope for the use of M. Adam-Salomon's alcove background and mode of lighting, but a modification of the principle might be applied. You do not state the position of the studio; but if you can get 12 feet side light on the north side, a very small amount of glass will serve for the south. We regret that we have not time to give private replies to photographic queries.

W. II. J.—You have surely not made yourself clear in ordering a mirror. An ordinary piece of silver glass would, of course, involve double reflection, but a mirror like that Mr. Edwards describes, being silvered on the surface, only reflects from that surface. We have seen such silvered mirrors, but cannot say by whom made. Probably if you write to Mr. Edwards he will inform you where his was obtained; but we should think that any manufacturer of philosophical apparatus would undertake it.

G. P. W.—Ebonite once cracked is very difficult to repair. We should think that marine glue would answer the purpose best.

S. HOGGARD.—The letter was forwarded.

J. GIRAULT.—The paper is attached, in Mr. Edwards's combination printing-frame, by being stretched over a piece of wood, over the edges of which the paper is turned, and, being pressed into a close-fitting frame, the paper is thus held firm. In Col. Stuart Wortley's frame the paper is, we believe, held in a similar manner. Where opal or other glass is used for the print, the plate is held in its place by means of a screw, in manner similar to the negative.

M. F. L.—That the correspondence was so lengthy is matter for regret, but the subject was of sufficient interest for insertion. The publication of your letter would not tend to shorten it. We do not approve the imputation of interested motives. Carbon printing will make its way, we have no doubt; but it is unfair to impute motives to those who hold a contrary opinion.

OWEN CHESTER.—Drying gum-gallic, or any other dry plates, on a shelf near the ceiling of a room hot with the burning of gas, will cause serious risk of spoiling the plates, as the products of the combustion of gas collected in the hot air will be decidedly injurious.

J. G.—It is absolutely impossible to answer a question depending upon so many uncertain conditions. Dry plates vary very much in sensitiveness. Light varies enormously. A "well-lighted interior" expresses nothing definite to base a calculation upon. It may vary from five minutes to fifty minutes. Unless an interior be very well lighted indeed, and the day very fine, we should hesitate to take an interior with a dry plate. A wet plate is much more likely to be successful.

F. D.—Herr Grune's method of enamelling by substitution of metals was patented, but the patent has been suffered to expire. If the subject had not been of interest, the correspondence would not have been suffered to extend so far. It will not extend much further, we hope.

B. M. A.—We do not know with certainty the price of silver at the Mint. So far as we know, it is worth about 5s. or 5s. 6d. per ounce.

F. E.—Col. Stuart Wortley intends, we believe, to exhibit his printing-frame at the next meeting of the Photographic Society, and the exact degree of resemblance between it and that of Mr. Edwards will be seen by all present. We have not yet seen that of the Colonel, and cannot, therefore, offer an opinion of value as to the degree of similarity. The publication of any rough opinion on a subject upon which litigation is imminent would be in very bad taste.

J. C. SMITH.—With M. Adam-Salomon's alcove background, side light—and, in some degree, top light—from the south may be controlled, but we should prefer to avoid the south top light altogether. 2. We should, in all cases, in building a studio, have the principal side light facing the north, if possible.

D. WELCH.—The print is a very good one, and the effect of leaf in printing very pleasing. It was, in the early days of photography, practised more frequently than now. You will find some valuable hints on the subject in an article on p. 15 of our Twelfth Volume.

Mr. F. A. BRIDGE.—Very neat. Thanks. We earnestly expect that all the correspondences in our pages will please or interest all our readers. It is sufficient that the subject is one of importance to many photographers to render it our duty to permit its appearance.

THE REV. S.—There are many articles on the gum-gallic process of Mr. Gordon, each giving hints of some especial point. We send a NEWS containing a moderately full statement of the process, and can send you others with other details if you desire. The numbers containing details of Petschler and Mann's process are out of print.

PYRO.—Thanks. In our next.

LIVERPOOL AMATEUR PHOTOGRAPHIC SOCIETY.—President's Address received too late for insertion in the present number. In our next.

Several Letters and Articles are compelled to stand over until our next.

Several Correspondents in our next.

MEDALS AT THE INDIAN PHOTOGRAPHIC EXHIBITION.

AN exhibition of photographs, under the auspices of the Bengal Photographic Society, has recently been held in the Dalhousie Institute, Calcutta. From the report of the jury, with a copy of which we have been favoured by the secretary, we learn that the exhibition has been highly satisfactory; and our readers will be gratified to learn that several English photographers have taken high honours. In the class open to all comers, Messrs. Robinson and Cherrill take two prizes out of the five offered—a gold medal for the best series of landscapes, and a silver medal for a series of portraits of children. Captain Lyon, whose magnificent photographs of Indian scenery have been exhibited at two of the displays in Conduit Street, obtains the gold medal for the best single photograph. Mr. Netterville Briggs, successor of Mr. Robinson at Leamington, obtained a silver medal for portraits. The report runs as follows:—

We have the honour to report, for the information of the Committee of the Bengal Photographic Society, that after careful inspection of the photographs now exhibited in the Dalhousie Institute, we have adjudged the prizes as follows:—

Prize A.—Gold medal for best single photograph, &c., to Captain Lyon for his picture numbered 511.

Prize B.—Gold medal for six pictures by a member of the society, not a photographer by profession, to Captain Taylor.

Prize C.—Gold medal for series of landscapes, to Messrs. Robinson and Cherrill.

Prize D.—Silver medal for portraits, to Mr. Netterville Briggs.

Prize E.—Silver medal for series of pictures by a member of the society, not a photographer by profession, &c., to Captain Senior.

Prize F.—Bronze medal for second best series after E, to Captain Swiney.

Prize G.—Silver medal for series of Indian subjects, exclusive of antiquities, to Dr. Brown.

Prize H.—Silver medal for photographs of Indian antiquities, by a member of the society, to Mr. Ravenshaw.

Prize J.—Silver medal for photographs of young children, to Messrs. Robinson and Cherrill.

Prize K.—Silver medal for reproductions of works of art, to Mr. Phillips.

We desire to draw the attention of the Committee to the great merit of the series of photographs of Indian antiquities by Captain Lyon. As this gentleman is not a member of the society they are not, as a series, eligible for a prize; but we have (with some difficulty in the selection among so many excellent pictures) awarded the gold medal (prize A) to his No. 511. We also wish specially to mention the excellent specimens of reproduction by photo-zincography exhibited by Lieutenant Waterhouse.

We have selected for distribution amongst members of the society the photograph to which we have adjudged prize A

(No. 511 of Captain Lyon's series), and one by Captain Senior, called "Jhoola and Sanga over the River Alaknunda."

We have the honour to be, sir, your obedient servants,

(Sd). E. GAY.

" THOS. S. ISAAC.

" W. G. MURRAY, Capt.

PHOTO-ENAMELLING PROCESSES.

The beauty of photographs burnt-in on ceramic surfaces is beyond controversy, their durability beyond cavil; and there are various processes of producing them accessible to photographers without trammel. Notwithstanding these things, the introduction of this perfect form of photography for portraiture lags strangely. For at least ten or a dozen years beautiful results of this process have been seen from time to time; at first, chiefly those of M. Lafon de Camarsac; next, those of other continental artists; and, during the last few years, not inferior to any, those of Mr. A. L. Henderson in our own country. The apparent apathy or indifference of photographers is here, as in relation to other new processes, due, doubtless, to several causes. As in the case of carbon, successful photographers have not, or fancy they have not, time for experiment in acquiring skill in entirely new operations; and unsuccessful photographers feel that they cannot afford it. Besides, they have felt that it involved risk, and it was difficult or impossible to get tuition. We are about to call specific attention to two openings for the latter purpose.

We have before mentioned to our readers the fortunate facility for seeing the operations and obtaining lessons in enamelling at the establishment of Mr. Solomon, in Red Lion Square. Our attention has more than once been called to an injustice to which we were unintentionally accessory in reprinting a notice of the late exhibition from an evening journal, in which some depreciatory remarks were made in reference to the examples of ceramic photography. In our own notice, we stated that these examples were far inferior to many we had seen produced in Mr. Solomon's establishment. They were, in fact, a few specimens from imperfect negatives hastily sent at the eleventh hour, simply to secure a representation in that department, and by no means fair examples of the work M. Walter Paul, operator at Mr. Solomon's, usually produces by the processes taught. For those willing to acquire a practical knowledge of this charming branch of portraiture, and to work it out, by patient skill, to perfection, these lessons will be very valuable, and the charge is comparatively insignificant.

The next facility for acquiring the photo-ceramic art claims still wider ground and higher terms. We have repeatedly referred to the high perfection of Mr. Henderson's enamels

as unsurpassed by the excellence of any others we have seen. For some time, Mr. Henderson has undertaken the production of enamels, not only for his own *clientelle*, but for the trade. His health does not permit him, however, to attend to his work with comfort, and he proposes to teach a certain number of photographers his method upon terms which will be found detailed in our advertising columns. The sum at which Mr. Henderson values his process is one thousand pounds. He proposes to divide this into forty sums of twenty-five pounds each, teaching forty pupils, each of whom will be placed under bond to preserve the secret. The whole extra cost for plant to carry on the process Mr. Henderson estimates at ten shillings; and he regards his process as so simple that skill in its practice may be easily and certainly acquired; and, as the prices obtained are generally highly remunerative, the first investment will very quickly be recovered by the photographer. We need only add our conviction that photenamelling is one of the coming branches of portraiture which professional photographers cannot afford to ignore.

Foreign Miscellanea.

THE photographic manipulators, MM. Quide and Meicke, who left Berlin at the commencement of the war to make observations at Strasburg and Metz, were last heard of as having gone into central France to lend assistance with the active armies, and are, it is supposed, with the Crown Prince's headquarters in the neighbourhood of Paris.

The method employed by the postal authorities in France for reducing, and afterwards amplifying, despatches and correspondence to be sent by carrier pigeon, was that described in Moitessier's book on micro-photography.

Dr. Stolze has made some special experiments in connexion with the use of organic substances in developing solutions, and has come to the conclusion that a cane-sugar solution, added in minute proportions, gives very good results. Milk, sugar, gelatine, caramel or burnt sugar, and glycerol, were all tried, but cane-sugar was the most rapid in its action. If a large proportion of sugar is used—say one-fourth of the quantity of sulphate of iron—a thick, slimy compound is formed, which hinders very much the development of the image.

M. Wolter—who has, it appears, been much occupied with the Lichtdruck process—lately called the attention of the members of the Berlin Society to the poisonous character of bichromate of potash. He complains of having suffered much from sores and eruptions of the skin upon the hands and arms, produced by coming into actual contact with the bichromate. The best remedy for these sores M. Wolter believes to be paper-oil, the liquid obtained by burning paper slowly and incompletely. According to M. Kruger, the healing nature of this oil is due to the presence of creosote, and therefore, possibly, ordinary tar would be just as efficient.

Professor Krippendorf publishes the final articles of his series of papers on Simpsontype in *Heliog*, detailing the manufacture and employment of collodio-chloride paper very fully.

Caution should be exercised just now in the purchase of pictures of the war. Many sham productions of this kind are, it is said, got up in Germany for the purposes of foreign markets.

In *Licht* appears an interesting article on the influence of sulphuric acid in the preparation of pyroxyline; it is from the pen of M. R. F. Poppe.

MM. Römmler and Hoffman, of Dresden, have elaborated a Lichtdruck process, the productions of which are said to leave nothing to be desired.

Some coloured and uncoloured collodion films were at the last meeting of the Dresden Society submitted to the inspection of the members by M. Motileff. These pellicles

are said to be of a hard and horny nature, and not liable to tear, being, therefore, very suitable for the support of negative or positive films, as likewise for the gelatine matrix in the Woodburytype method. The inventor stated that the cost of these films depended upon the quantity of material necessary in their preparation, and promised further particulars as soon as the matter had been fully elaborated.

The establishment of M. Reutlinger at Paris has been carried on uninterruptedly during the siege, as many as eleven employes having been engaged therein during the time. Communication with the head of the firm was maintained by balloon post. Indeed, it would appear from the invaluable use made of photography as a means of facilitating correspondence with friends outside the walls, that Parisian operators have been busily employed during the four mouths of the besiegement.

M. Hallenbeck, in the *Archiv*, says that an addition of four drops of oil of cloves per ounce of collodion (30 grammes) renders the same very sensitive. An almost instantaneous collodion may be ensured by dissolving one drop of pure cod liver oil in eight grammes of ether, and adding this to fifteen ounces of collodion.

The constitution of the Vienna Photographic Society has undergone great change. The president, M. Martin, and secretary, M. Schrank (late editor of the *Correspondenz*) have resigned, and in their stead have been chosen Dr. Hornig as president, and M. Jenik as secretary. Among the committee are to be found the well-known names of Ludwig Angerer, Fritz Luckhardt, A. Melingo, Ludwig Schrank, Carl Krziwanek, C. Haack, A. Martin, &c.

In the *Journal der praktischen Chemie*, M. Böttger enumerates a series of experiments recently undertaken with some double iodides, which, on being warmed, undergo a change of colour.

Mr. Woodbury has recently written to the Berlin Society for the Advancement of Photography to correct some misunderstanding which seems to have prevailed in regard to the capabilities of the London Woodburytype establishment. In his letter, Mr. Woodbury states that instead of being able to produce but 200 prints daily from six presses, it is possible to turn out as many as 8,000 cabinet pictures per diem, or double that number of cartes-de-visite, there being as many as thirty printing presses now at work.

When a plate has been kept so long in the frame that it becomes dry before development, and its surface is covered with star-like crystals, it is a good plan, says the *Archiv*, to coat the margin of the film with shellac varnish, and then to immerse it in an unserviceable silver bath. In this way the crystals are soon dissolved away, especially if a little agitation of the liquid is caused, and the plate may then be operated upon in the usual manner.

According to the *Archiv*, the Victoria card has made way in the Rhine Provinces, and in Westphalia. Many photographers have been doing as much business in them as in cartes-de-visite.

A CHAT ABOUT THE VICTORIA CARD.

BY "PYRO."

MANY are the valuable hints given by the Editor, with a view to stimulate photographic enterprise; and his able advocacy of all matters possessing a prospective source of profit shows how mindful he is of the interests of his subscribers. Yet how rarely are these hints acted upon by those for whose especial benefit they are gratuitously given! This seeming indifference and reluctance on the part of professional men to break from their come-day go-day system is much to be regretted, and cannot fail to act prejudicially to their interests.

Anything which tends to give an impetus to business should heartily commend itself to the serious consideration of every man whose power of vision is not confined to the limit of his nose. Prompt action in the adoption of new ideas is the characteristic of our American and continental

brethren ; but, unfortunately, with us the reverse is the case. The future of photography will depend more and more upon the energy and skill displayed by its professors ; therefore it behoves us to exercise all possible ability, combined with tact and perseverance, in order to secure anything like commercial success.

The liberality of Mons. Salomon, Blanchard, Robinson, and others, in communicating their experience, has had due weight (in an artistic sense) with the intelligent portion of the photographic profession, and the growing desire to follow in the footsteps of these masters of the art has a cheery and healthy look for the future.

But while we are fully alive to the manipulatory excellence as displayed in the work of the present day, and which has undoubtedly been brought about by the masterly examples of the gentlemen referred to, we should not be unmindful of other sources, which might furnish still further facilities for progressive improvement. In the adoption of the Victoria Card we have all the promise of an artistic novelty and a commercial success. The extra marginal space gained in this new size of card would afford increased scope for the display of pictorial effect, and, in other respects, would be a decided improvement upon the present miserable cramped productions. The increasing demand for large bust pictures and three-quarter portraits imperatively calls for some more suitable size, and more especially is this want felt in those portraits of large heads, the scanty margin of which robs them of character, depth, and finish. I verily believe that this new style of picture would completely revolutionize the present state of things, and create a demand second only to the carte mania.

But in order to accomplish this very desirable change, it is essential that there be little or no deviation from the present rate of prices. Of course, my remark does not apply to the three-and-sixpenny gentlemen, but has reference only to prices consistent with good work. This I hold to be a *sine qua non* to success, for I have no hesitation in saying that the partial failure of the cabinet portrait in this country is solely attributable to the extra charge. The gay Parisian thinks little of his gold napoleon provided there is pleasure at the end of it, no matter what form that pleasure may assume ; and equally indifferent is the owner of the almighty dollar ; but your sober Briton invariably looks twice at his shilling before he parts company, hence the desirability of providing a novelty without making any alarming inroad upon his pocket. There are doubtless many difficulties and prejudices to overcome, but, once the thing is fairly set going, there need be no fear of a successful issue ; and, as the interest of the album manufacturer is identical with that of the photographer, it would manifestly be to the advantage of both to bring the matter prominently before the public. The former, by at once applying himself to the manufacture of a suitable and moderate-priced album, and thoroughly pushing it through the country ; and the latter, by the aid of advertisement, by the introduction of new and artistic show cards, and otherwise, by every available means in his power, giving publicity to the same. That photography requires some really attractive feature to rouse it from its present lethargic state is the humble but firm conviction of one of its votaries.

ON THE USE OF THE LIME LIGHT IN MICRO-PHOTOGRAPHY.]

BY CARL HAACK.*

The production of extensive enlargements in micro-photography is often a task beset with difficulties, from the fact that sunlight is usually required for the purpose ; for without the aid of the sun it is impossible almost to obtain sharpness, except in the middle of the image, so that the dimensions of the latter are confined to a small compass. Photographs of small size—of an inch or two in diameter—when the magnifying power is not very great, may, it is

true, be produced by means of diffused light ; but when the diameter of the illuminated field amounts to five inches or thereabouts, sufficient light cannot be obtained to yield a satisfactory result unless the sun is shining ; and as in winter it is rare that we have an opportunity of enjoying sunlight, it is well to be able to resort to artificial illumination as a welcome alternative.

With a good petroleum lamp, enlargements of a sketchy nature may be produced when the object enlarged is free from colour ; but any trace of the latter materially interferes with the result. In the lime light, however, we have a source of illumination twenty or thirty times as powerful as that of a petroleum lamp, and one, therefore, which should satisfy all our wants.

Besides the lime light, there are the magnesium and electric lights, which have been recommended for purposes of this nature. To the magnesium light there is the twofold objection of its expense (one hour's consumption costing about five florins), and the unsteadiness of the flame, the burning wire causing a trembling of the illuminated field upon the focussing glass, and even of the image itself under certain circumstances, and thus producing an indistinct picture. The electric light exhibits the same defect, from the fact that the two carbon points cannot be maintained in perfect repose during the employment of the lamp ; and there is, moreover, the circumstance of maintaining in order a large Bunsen battery of some twenty elements to be considered.

For enlargements up to seven hundred diameters, it is sufficient to employ a spirit-lamp with the lime light, in place of either hydrogen or coal-gas, so that one has only to trouble oneself about the oxygen. The latter is conveyed to the flame by means of a very fine tube, being blown upon the surface of the cylinder of lime or magnesia, and thus forming a small bright spot. This illumination thus afforded, by the use of Plossl's system F in combination with No. 2 eye-piece, and with a camera drawn out about one foot and a-half, will yield an enlargement of seven hundred diameters after an exposure of five minutes with a wet plate. If precautions are taken to prevent the desiccation of the plate, so that an exposure of twenty minutes may be given, an enlargement of 1,400 diameters may be secured with the camera pulled out to twice the above named distance. When hydrogen is used in combination with the oxygen, the intensity of the light is increased, and a shorter exposure is then required.

The above data are based upon the enlargement of colourless objects—as, for instance, diatomæ—those of a tinted nature necessitating longer exposure. To prevent the drying up of the plate, I find it the best plan to cover over the prepared film with a sheet of thin white plate glass of the same dimensions, upon the margins of which very thin strips of whalebone have been cemented, to prevent any contact with and injury to the collodion. In this way the evaporation of moisture is prevented, and the collodion plate may remain exposed for a full hour without deteriorating in any way. If, however, one operates in a cooler locality than that in which the plate was first prepared, it is often the case that a condensation takes place upon the protecting glass, thus rendering the image blurred and somewhat under-exposed. To remedy this, the glass should, in the first instance, be coated with a very thin and carefully filtered solution of gelatine or albumen, and allowed to dry, when it will be found that even by breathing upon the surface no deposit of moisture takes place to destroy or impair its transparency. Other methods for preserving the collodion film in a moist condition—as, for instance, the addition to the silver bath of such substances as nitrate of magnesia, glycerine, &c.—are, according to my experience, either injurious to the sensitiveness or clearness of the film. If an hour's exposure is not objected to, it is best to use a dry plate at once, which will be found to give a finer picture than a wet negative. For enlargements of from fifty to two hundred diameters

* *Photographische Correspondenz.*

an exposure of from half to two minutes suffices with a wet plate.

As only a very small illuminating source is necessary—of, however, the greatest possible intensity—one cubic foot of oxygen will suffice for the production of four to eight negatives if an economical arrangement is made, and the preliminary rough focussing of the image is conducted with the aid of a petroleum lamp. The preparation of a cubic foot of oxygen from chlorate of potash costs but about fivepence, and the manipulations necessary for the purpose are quickly and easily performed.

The jet of the gas should be so constructed that it may be approached to or receded from the spirit flames and lime cylinder, so that the stream of gas can be directed towards the hottest portion of the glowing material. Especially suitable for the purpose are the burners devised by Dr. Monckhoven for his enlarging apparatus, with which, if desired, the spirit lamp may be employed instead of a second gas. The artificial magnesia cylinders, too, which have been referred to in this journal, are more readily heated to a glowing whiteness and yield a brighter light than columns made from ordinary burnt lime, the occasional burning away and hollowing out of the former during combustion having no material influence upon the character of the light.

To render the light more intense, and also to lead the rays in a proper direction, it is necessary, as in the case of Monckhoven's enlarging apparatus, to employ a condenser of but small dimensions. This consists of two plano-convex lenses of short focus fitted together, the illuminating source being placed in the focus of one lens. From this the rays go in a parallel direction through the second one, which, again, projects at its focus on the further side a circle of light, and according to the lens employed this circle is thrown either through the object in the optical system, or allowed to coincide with the object itself.

The condenser should be perfectly achromatic, and, if possible, also aplanatic, and possess a focus of from one to two inches. If the dimensions of the same are large, more light is, of course, concentrated; but then, again, the length of focus being increased, the source of illumination must of necessity be placed at a greater distance. It must be remembered, too, that the intensity of the light diminishes by the square of the distance. Satisfactory results have I obtained by employing Plossl's No. 1 eyepiece as condenser after the lenses had been placed at a less distance—half an inch—from each other, the same data as above mentioned in regard to exposure being found suitable for this condenser.

According to the position of the lenses is the object illuminated in various ways, either with converging rays when the focus is behind, or with diverging rays when the focus is in front of the object. One may work also with parallel rays if behind the condenser a diverging lens is placed. The first mode of lighting up is that most suitable for the majority of instances, although it is quite impossible to draw up any general rules on the subject. It is necessary to study carefully the object, in the first instance, before a decision can be arrived at as to the method of illumination which reproduces the greatest detail. It may, however, always be considered certain that when weak lenses are employed the focus should fall into the system, while with powerful ones the focus must fall upon the object. In the latter case the greatest amount of light is obtained just where, on account of the light weakness of the lens, it is the most required.

If the condenser happens to be too close to the object, one obtains traces of light defraction upon the picture, which operates very injuriously; the eye is, however, soon accustomed by practice to find the proper place for the condenser when focussing the image upon the matt glass. The whole illuminating system must be so arranged that it may be easily removed from the axis of the microscope

when necessary, or made to send the rays in a slanting direction or from above in the case of opaque objects. If compelled to employ a mirror for the purpose of reflecting the light from its direct path, the surface of this reflector must only possess one surface—or, in other words, it must be a polished metal plate, or a glass silvered upon the surface. In the case of the latter, should the reflector be dulled or injured in use, its pristine brightness is easily restored by any of the well-known methods of re-silvering.

The focussing of the image is managed by pulling out the camera gently in the ordinary manner, and is effected upon a well oiled fine matt screen; in very fine objects a piece of plate glass should be used instead of ground glass, the image being viewed by means of a magnifier, and focussed upon the surface nearest the lens. If a very long camera is employed, as in the case of extensive enlargements, so that the operator cannot work the screw of the microscope himself, it is best to avail oneself of Moitessier's proposition to have a telescope, which, fitted through an opening in the camera near the lens, allows one to observe the image when falling upon a white sheet of paper, which serves as focussing screen; a sharp definition of the image is then secured by moving the back of the camera.

If it is desired to work with monotone light, in order to compensate for any difference of focus in the lenses, there may be easily fitted up, between the condenser and the object, a small bath with plane-parallel sides, filled with a blue solution. A solution of sulphate of copper and ammonia is best suited for this purpose, but as, in this mode of proceeding, a certain amount of light is always lost, it is best to ascertain the focal difference of each lens by previous experiment, and to bear it in mind, so that it may be corrected upon the focussing screen.

In all other details the apparatus for micro-photography does not differ far from that hitherto in use. Whether arranged horizontally or perpendicularly, for large or small pictures, artificial light may always be used; but as it is not my intention in these lines to describe in detail the different apparatus that can be employed, and which, by the way, are fully enumerated by Moitessier and Bennecke, I must refer the reader to the books of those gentlemen for any further information. My purpose, on the present occasion, is merely to call attention to the advantage of employing the lime light in manipulations of this kind, and thus to render the operator independent of the caprices of the weather.

THE SOLAR ECLIPSE IN SICILY.

BY DR. H. VOGEL.*

SHORTLY after passing over the lava, we came into a steep forest region, not such a forest as one sees in Germany, but consisting of stunted trees, mostly oak, sparsely scattered about. Our way now lay up a narrow gorge, having for its bed a narrow lava stream, of which there are many to be seen in this region. During our ascent the sky became overcast, a strong northerly wind arose, and heavy suspicious looking clouds drifted over the mountain. Affairs became worse as we progressed, and, suffering personally from an attack of rheumatism, my position was by no means a comfortable one. At last we reached a stony hut on the margin of the forest, a sort of rough hunting box, and here we took up our quarters. A barometrical reading showed our height to be 4,800 feet, and by reason of the boisterous nature of the wind, the badness of the weather, and the guide's statement that a hut situated higher up, called the Casa Inglese, was difficult of access, it was decided to remain altogether at the Casa Ferentina. But a very limited view was possible over the landscape; the Bay of Catania and the Lake of Lentini were visible, but the clouds narrowed the prospect very much. Night came on, and the provisions we had brought with us pro-

* Continued from p. 67.

vided a frugal supper. A capital fire was made up on the hearth, which warmed, in some degree, our stiffened limbs, and Professor Roscoe, by way of an agreeable surprise, provided us with some chocolate of his own making. Our party consisted of one American (General Abbott) and one Italian (M. Silvestri), a chemist of Catauia, to whom I am under some obligation for friendly assistance in the way of chemicals and apparatus from his laboratory, and aid in the organization of my arrangements; M. Silvestri was detailed to undertake physical observations. Then there was Professor Roscoe, with his assistant, Mr. Bowen, for spectroscopic work; Mr. Harris, for the polariscope; and Mr. Darwin, who was to sketch the corona. Thus every necessary preparation was made and arranged, there being, indeed, only one thing else to be controlled, and that was the weather, which appeared likely to set at nought all our endeavours. The wind became a storm at midnight, and whistled through the hut in so gruesome a manner as to make one believe that not only earthly, but also subterranean, powers were at work, for we were, in truth, sleeping literally upon a volcano. As we sought our couch of straw for the night, the rain poured down upon the roof, changing soon, however, into sleet and snow; the fire was maintained during the whole of the night, during which, however, we could sleep but little; and on the next morning we found the hut surrounded by a fall of fresh snow, while dense clouds impeded our view altogether. Professor Silvestri made a barometrical observation, and found the column had fallen 7.9 millimetres since the previous evening. Matters appeared critical, and in the meantime our guide arrived from below (he having returned to our starting point during the night) with the intelligence that fine weather prevailed at the foot of the mountain. Under these circumstances we discussed the advisability of descending at once and making our observations at Nicolosi. At eight o'clock, however, the sun suddenly burst through the clouds, the wind dispersed the mist, and we saw above us the snowy summit of Mount Etna. Hope inspired us, and we at once set up our instruments. I forthwith took a few photographs of ourselves and also of the landscape, and found the intensity of the light to be extremely great. One misfortune befel me: while developing a plate in the tent, the guide, notwithstanding my strict instructions to the contrary, left my American camera, and this, carried away by the wind and storm, fell into an old well-shaft. I was astonished, on my return, to find both guide and camera gone; the first I discovered chatting quietly with his companion, while the second I found, to my horror, broken into pieces at the bottom of the shaft. Fortunately, the freshly fallen snow had considerably broken the fall, and the damage was found to be repairable, for the excellent Busch lenses had not suffered in any way. We therefore made ourselves ready for action, and arranged our instruments suitably for the observations. I worked with two cameras, my idea being to prepare the plates ten minutes before the eclipse, and to expose during totality.

There came up, however, shortly before a quarter past twelve, a yellowish cloud of monster proportions, just as we were observing the first contact. The cloud came nearer and nearer, partially covering the sky, and we watched it with bated breath as it began slowly, but perceptibly, to increase in size. Presently the solar sickle could be seen only partially through rents in the clouds, and then the mist began to form an impenetrable homogeneous mass, while a storm of hail rattled down upon us; there was no alternative but to withdraw our delicate instruments from the fury of the tempest, and take them under cover; and in this situation it was that totality arrived. My plates were ready; five minutes before totality I exposed one portion of the plate in the direction of the sun, now covered with dense mist, giving an exposure of thirty seconds. Soon it became darker, and one minute before totality I repeated the experiment; then

came totality: first, a greyish blue glimmering, then a dark grey atmosphere, but yet light enough to enable one to distinguish the time on a watch, and the other observers standing in the snow some hundred paces off. I exposed my plate again during totality—viz., at three minutes after two—giving an exposure of sixty seconds. At the close, it became suddenly lighter around us, a peculiar rosy haze enveloping us, which soon changed into the ordinary light of a grey, misty day. The phenomenon which had brought us hundreds—and some even thousands—of miles to witness, which had cost great trouble and study, besides much time and money, had past away, and was, for us, irrevocably gone; our efforts and exertion had been, indeed, in vain. In a storm of rain and hail we packed up our instruments, and twenty minutes afterwards the clouds broke up and the sun came out as if to mock us for our pains.

I developed the plate I had exposed to the clouds. The first third thereof (exposed five minutes before totality) exhibited but a slight action of light; the next third (exposed one minute before totality) had been affected, but in a less degree; and the last third of the plate (exposed during totality) afforded no trace whatever of any chemical action. It is, nevertheless, probable that a chemical action does exist during totality, from the fact that the shadow of the moon covers only a portion of the blue sky, and there remains some portion on the further side of the eclipse margin which reflects active light rays. Against our own misfortune, however, we could bear up; but we feared that as the cloud passed off in a southerly direction to Catania and Augusta, the same would also upset the arrangements of our friends at those points; and so, indeed, it turned out.

Shortly before the end of the eclipse, General Abbott and three amateurs from Vicenza arrived at our hut, having been stationed higher up the mountain, without, however, enjoying better fortune. Hastily we packed up our apparatus, and turned our faces at dusk towards Nicolosi, flashes of lightning being visible every now and then in the unclouded landscape.

At Nicolosi we fell in with the American Professors Peters and Einbeck, who had seen even less than ourselves. Only the last phase of the eclipse had been visible to them, and Einbeck had been able to recognize Venus in the vicinity of the sun. After partaking together of a convivial meal we returned to Catania, where we found some other observers—Lockyer and the American photographers—who had only seen the last five seconds of the eclipse behind the clouds. Chapman had been able, by means of an ordinary, but very powerful, lens, to obtain a picture of the sun among the clouds during this short interval. From Fort Augusta the intelligence we received was hardly more satisfactory; and everywhere, indeed, were heard complaints of the weather; at Syracuse alone were the results at all good, and here five pictures were obtained during totality, among which were two of the corona.

Those most favourably situated were Professors Pierce and Watson, of America, who watched the corona from a country seat belonging to the Marquis of Guiliano, where they were able to observe its profile, structure, and spectrum. The polariscope observer found that the light of the corona is polarized, and by means of spectroscopic results—the details of which will be published hereafter—it was positively decided that the corona belongs to the sun itself, and is not due to the atmosphere of the earth. Watson saw it in the form nearly of a perfect circle, seven minutes in height.

Of the fortunes of the Italian photographers at Fort Augusta we have, as yet, learnt nothing. Large masses of protuberances were observed during the totality, and despite, therefore, the unfavourableness of the weather, the results obtained are really very important. Let us hope that the observers in Spain, Algiers, and Tunis were favoured with better fortune than ourselves.

THE COMING SEASON, AND WHAT SHALL WE DO IN IT?

BY E. DUNMORE.*

"Coming events cast their shadows before." So the season for increased activity among the photographers—or, I might say, as far as Londoners are concerned, an awakening from a state of torpor—will, it is to be hoped, shortly arrive, when a general overhauling of out-door apparatus, cameras, &c., will take place, new processes tried, or, at least, experiments on an extended scale made, and the shadows that are cast will be caught and boxed by hundreds of amateurs and professionals. We will now consider how these said shadows can be most advantageously collected.

With the exception of a more extended scale of dry-plate processes, photography remains much in the same state as for several years past. The same rules require observation, and the same sequence of manipulations is adopted. The most conspicuous alterations consist in the finished proofs, and not in the negatives themselves. Land and sky must, in all cases, receive separate treatment. In these utilitarian times the majority of photographers confine their attention to the smaller class of pictures in preference to the more artistic and imposing sizes; for there is no doubt that, at present, the smaller sizes pay best, any more than there is no doubt that large size is an important element in making a general and favourable impression on the picture-loving public. The commercial and artistic sides of the question in this particular certainly do not pull together kindly; if we can by any means make them do so the advantage to all will be apparent.

It is evident from the careful study of exhibited works that many of those photographers who seldom get beyond the 10 by 8 size, and never produce large pictures, are quite capable of doing so, if their attention were turned to it, as those who have really done so. We may safely say that it is not for lack of skill that large pictures are so few and far between. That the enlargement of small negatives can be very successfully achieved we know; but unless the original small negatives are expressly *arranged* and taken for this purpose, they only disappoint, and end in failure. An artistically grouped picture, with cleverly managed light and shade, on a small scale, is, nine times out of ten, poor, tame, and insipid when enlarged many diameters; grand masses of light and shade turn out patchy and spotty, and in the wrong places.

Some will ask—How shall we avoid it? Simply by cultivating our judgment, and paying *more* attention to nature herself, and less to the focussing screen. There must be, of course, more artistic talent brought into play to make a large successful picture than a small one, as a mistake is so much more conspicuous, and makes itself felt, where, in a small work, it would be overlooked. These are matters, however, easily remedied. I would recommend photographers to take one or two negatives in the coming season, especially for enlargement, when a happy combination of place and circumstance put such in their way as suitable subjects. The cost would be but trifling, and the satisfaction and beauty of the resulting picture amply compensate for the trouble. Two or three hundred clever pictures on whole-sheet paper (23 by 18) would form an exhibition the like of which the British public has never yet had the opportunity of admiring. Who can tell what such an exhibition would do for the interest of photographers, commercially and æsthetically? Every photographer who possesses even the most diminutive of apparatus has it in his power to aid in such a display, providing he has the requisite art culture.

As to the enlargement, I believe there are many firms who would undertake that part of the business where the photographer cannot do it himself. Enlarged paper negatives seem to be most suitable, as the resulting print is so much more under control. The production of such paper

negatives, probably, might become an industry of itself, extensive and remunerative.

We will now, without making any invidious comparisons, consider what are the most suitable lenses to use for ordinary outdoor work, and to what uses the different lenses are to be applied—what to do and what to avoid. We must first consider the class of subject and the effect desired. Much licence is allowable in this respect, and will vary, of course, with the ideas of the operator. If the subject be required to give the truest impression of itself, the old single landscape lens will, perhaps, be best, as I think a picture of this kind will convey a more truthful idea than a wider angle or shorter focus combination.

If an artistic study be required, a short focus wide angle lens is most suitable. More of a picture will result from its use, but a great depends on how it is used. Much more, in my opinion, depends on the operator than on the lenses. These remarks apply to landscape, not architectural subjects. Each has his own peculiarities as to the kind of picture he prefers—so much so, that little difficulty is found in attributing a picture to its author, if many from the same man have been before the public. Certain rules must be complied with, no matter what each artist's mannerism (not to use the word in its objectionable sense) may be. Never will short-focus lenses with wide angles be suitable for distant views, or long-focus ones for near views.

Opticians tell us that good lenses do not distort. Possibly not; but the public are not opticians, and are apt to be rather arbitrary in their opinions, and in matters of this kind public opinion will not knock under to scientific reasons. I allude especially to exaggeration of near objects when wide-angle lenses are used; therefore, in this respect, our course is more or less decided for us. With the variety of lenses at our command, we should never be at a loss in this respect, and use suitable lenses as painters use suitable brushes.

With regard to cameras, the two most important matters are rapidity and lightness. I cannot help thinking a thin metallic dark slide, containing a moistened felt pad, would be a great improvement on the wooden one; also, by having the carrier hinged, with its wire corners so adjusted that a thin piece of glass could be habitually kept before the sensitive film, and the back of the dark slide to be solid, and not removable. Both plans have been before suggested, and I can answer, from experience, that the plate of glass before the film is a great improvement, as it prevents dust and evaporation, and, I should suppose, immunity from those tantalizing shell-markings in hot weather.

As to tents, the most portable are not always the most pleasant to work in. Give me plenty of breathing room, even if the tent be rather bulky; for, if a hard day's work is to be done, much is saved in fatigue by a roomy tent. The ether and acid vapours in a small one in hot weather are trying in the extreme, and the day is finished with headache and exhaustion. I allude to wet-plate work, for, until some plan be found for quickly and easily developing dry plates that have an equal sensitiveness to wet, this process will still remain the process for professionals, as it is frequently an imperative necessity to know what sort of a picture you have taken at the time.

As to developers, most photographers have their own pet formulæ. Taking it double strength, and diluting when wanted, saves space, and is a satisfactory plan. In hot weather much should not be prepared at once, as it seems to lose energy. The use of methylated spirit, instead of rectified, frequently predisposes to dirty markings on the plate. Concentrated developer kept in gutta-percha bottles soon spoils in summer. There is nothing like glass, notwithstanding its breakable qualities. I am, perhaps, stringing together a lot of truisms, but it is just as well to give old but useful experience a fillip now and then.

Lastly, with regard to collodion bottles: a two-necked bottle—one neck containing a filtering medium, so that in no case is the collodion returned to the bottle without fil-

* Read at a meeting of the South London Photographic Society, Feb. 9.

tration—is a good plan to avoid comets, *et id genus omne*, and a little apparatus that can be easily made. If our apparatus makers would construct a half-pint bottle for this purpose I can venture to predict a good sale for it. Until they do we must make them ourselves in this way:—A wide-mouthed bottle of the requisite capacity, supplied with a good cork perforated with two holes, into which insert two tube bottles with their bottoms removed; the one for the filter must have a piece of fine cambric, once or twice doubled, tied carefully over the open end, and the bottle partly filled with cotton-wool. This strainer tube to be passed through the cork low into the collodion; the other tube, as it will be used to pour from, pushed just through the cork, that is all. The advantage of having the strainer continually in the collodion is to keep it always moist and in filtering order. With these precautions I do not see how it can very readily get wrong, and would be a decided improvement on the ordinary bottle.

Correspondence.

PHOTOGRAPHING IN COLOURS.

SIR,—I am an artist, not a photographer, though I have practised a little for amusement; and finding some photographers had an idea that printing in colours was possible, and some with not the slightest hope, I thought, as I had studied and practised my ideas for some time, I would explain a few of them, though I have not arrived at a favourable result as yet; but it is owing, I believe, to not having time to spare to experiment further; but I will endeavour to prove the improbability of its being accomplished mechanically. Take a flower in bud (I prefer buds, because the action of the sun's rays has not attracted the colouring matter to the surface wholly) of any colour, and procure a piece of the best absorbent paper, and place the bud upon it; then over it lay a sheet of thick glass, and place on the top as heavy a weight as it will bear for a short time; then remove the glass, &c., off the paper, and expose it to the rays of the sun for a time, and the colour of the bud, though not perceptible before, will gradually appear, and if the bud was variegated in colour, it will be repeated on the paper, though faint and confused; if a leaf of the bud alone were used, it would appear more definite. Take a quantity of buds of colours in tints as near one another as possible, and place them between two glass plates, the bottom one with grooves round the edges to allow the liquid to run in; drain it off in a very small phial, clean the plates, and do buds of another colour, till you have pressed separately from a yellow to a purple. Then procure a piece of paper, and, having a brush for each phial, brush half of its section with the various liquids; on the other half drop a few drops from each phial, and amalgamate them with a separate brush, and place the paper with a negative in the usual manner in a frame, and expose it to the sun's rays, and where the liquid was amalgamated the shadows will appear in time of a dull weak tone, and where it was sectioned the image will be variegated in colour, though faint. The idea may strike some, that if the colouring matter was applied to the negative glass prior to exposure in the camera, the coloured rays falling on the plate would attract the colouring matter that composed yellow or blue to parts of the plate that received that reflection through the lens; but if you, before putting the sensitized plate in the slide, drop separately, on various portions of the plate, the liquid out of each phial, and then mix in a separate phial a few drops from each, and drop that on another portion of the plate, and expose, &c., when the plate is dry you can trace, but very imperfectly, the various tints, and where the mixed liquid was put upon the plate it will appear a shade duller. Carbon process is the one, I believe, which is most likely to arrive at producing prints in colour; if you get some powder colours and some dissolved gelatine, and place a little of each colour in sepa-

rate saucers together with the gelatine, and grind them, then place a negative, and with the paper towards you, so that the light passes through the image and paints the paper, as if you were colouring a photo in flat tint, then expose for a time and wash the superfluous colour away, you will have a coloured image—far from perfection, but as near, I believe, as possible. If printing in colours were possible, the print would be tame and flat, and lack the brilliancy that is desired and expected from the hands of the artist. But if photographers would try experiments, and not wait for chemists to place within their reach some magic liquid, they would come to a decided conviction of its difficulties and improbability.—Yours respectfully, T. SLEIGH APPLETON.

49, Stretford Road, Manchester.

OWNERSHIP OF NEGATIVES.

SIR,—At various times letters have appeared in the PHOTOGRAPHIC NEWS respecting the ownership of the negative. A few days since I came across the letter written by Mr. Le Neve Foster, in May, 1869, referring to that subject. As the matter closely concerns portrait photographers, it may be useful to them if I endeavour to define their position with reference to the copyright of portrait negatives.

Copyright in a commissioned work is entirely a matter of contract, and all contracts must be made with precision, whether written or verbal. Mr. Foster says the photographer has a chattel interest in the negative, subject to certain restrictions, one of which is, "he may not use it to the prejudice of the copyright which the law has vested in another party, that party in the present case being the individual giving the commission. The lithographer's stone remains his property subject to similar restrictions." Now, with due respect to Mr. Foster, I must differ from him. The Copyright Act is directed against piracy. From a legal negative a piratical photograph cannot be printed, therefore a photographer printing copies from such a negative against the wish of the sitter cannot be prosecuted under the Copyright Act. No action for damages under the Engraving Copyright Acts will lie against a lithographer for printing copies against the will of his customer. If a photographer gibbets his sitter against his advertising door-post, he incurs no penalty under the Artistic Copyright Act. If Daguerreotypes and glass positives were now in fashion, the copyrights therein would, as a matter of course, vest in the sitters; but they are no longer produced. In the present day, if a sitter wishes to possess the copyright of his portrait, it is absolutely necessary that he contract in precise terms with the artist. He may say to the artist, "I wish you to take a photographic negative of me, for which I will pay you your price." The money must be paid, and then the copyright vests in the sitter, who may direct the photographer to print so many copies, and no more. If the price agreed upon exceed ten pounds, the contract must be in writing, otherwise it will be void under the statute of frauds. The photographer prints the number of copies agreed upon, and perhaps prints more; perhaps, Mr. Foster to the contrary notwithstanding, he gibbets his sitter on his advertising door-post. The sitter is aggrieved, but where is his remedy? The Artistic Copyright Act will not aid him, for there is no piracy. He might apply to the Court of Chancery for an injunction, or he might proceed by action at law, or by plaint in the County Court for breach of contract. These, I think, are his only remedies. If the photographer, however, were to make a negative from the original negative, or from a proof thereof, he would produce a piratical photograph, and bring himself within the operation of the Act.

Now I think it very rarely happens that sitters and photographers do make contracts in the manner I have supposed. What generally happens is this: the sitter contracts for so many copies of his portrait at a price, and, as copies are not originals, the question of copyright does not arise. The statute, no doubt, contemplates vesting the copyright

in the sitter, but the statute only refers to original works; it is, therefore, necessary that the sitter should expressly commission the execution of the negative; as, generally speaking, he only commissions copies, he acquires no copyright. In all cases, if copyright is to be created, the negatives must be made for a good or valuable consideration. It is clear that where the sitter contracts only for copies, he has no right to the negative, and acquires no copyright. In ordinary parlance, the word original has a use more extended than it has legally. When an artist paints two or more pictures of the same subject, we speak of them as original works; the law recognizes as original only that work which is first produced. We speak of photographs as being original when they are only copies of an original, viz., the negative. Certain works of art we call engravings, when they are copies or impressions from an engraved plate. The term copyright has also a wider general use than it has in law. "Copyright engravings" applied to impressions is a misnomer; they are not engravings, neither are they copyright. The engraving is a metal plate, and the copyright is an incorporeal right existing collaterally for twenty-eight years upon certain conditions. Many persons, magistrates and aldermen included, appear to have very hazy notions of the meaning of the term copyright. Some of your correspondents speak of large sums given for copyrights of engravings. We know very well what they mean, but, actually, the copyright of an engraving costs nothing; the expense of engraving a plate is the same, whether it be copyright or non-copyright; they allude to the price paid for the permission or right to engrave, which is quite another matter.

Prior to 1862, copyright in a painting or design did not exist. It is true, before a design was exhibited or published, the owner had a right, at common law, to prevent any person from copying it without his consent; but that is only a negative right or power to prevent copying, and not a positive sole right of reproduction. The owner might have copies made, but the moment he parted with them his power to prevent others from making copies would cease. Sir Thomas Lawrence was, I believe, the first British artist who received money for permission to engrave his works; from his time to 1862, it was a common practice for artists to sell to publishers permission to engrave their works, and this was called selling the copyright; but as, during that period, copyright in paintings, &c., did not exist, it could not be bought or sold. Publishers, although they had paid for permission to engrave certain works, obtained thereby no power to prevent other persons from making copies of those works if they could get access to them. This is illustrated in an action brought by a publisher against an engraver. The engraver was commissioned to make an engraving from a certain design. He engraved two plates from the design, one of which he handed to the publisher, the other he kept, and from it printed and published copies. The publisher brought an action for piracy, and was non-suited upon the ground that as both plates were made from the same design, the one could not be a piracy of the other. Copyright is defined by the statute 5 and 6 Vict., cap. 45, sect. 2, to be "the sole and exclusive right of printing or multiplying copies;" it therefore follows that unless a person possess the sole and exclusive right of reproduction, he does not possess copyright.

At the hearing of a case for infringement of copyright, I once heard an alderman remark that "there could be but one copyright in a design," which is quite true; but in his adjudication he recognized two copyrights—namely, copyright in the design of the original painting, and copyright in the design of a photograph taken from an engraving of the painting, thus stultifying his own words. If copyright in the design existed at all, it would be in the design of the painting, and nowhere else. As the law is at present construed, a photographer may maintain copyright in a photograph taken from a painting, because he is the author of the photograph; but he is not the author of the design, and

therefore has no power to prevent others from reproducing it, provided they do not use his photograph.—I am, sir, your obedient servant,
J. CUNNINGTON.

London, January 30th, 1871.

DISSOLVING VIEWS WITH ONE LANTERN.

SIR,—Would you allow the insertion of a few words, which shall be the *last*, in answer to Mr. Martin's letter? Mr. Martin, in last week's NEWS, by a wilful perversion of imagination, says: "That 'Silvester,' perceiving his mistake, has hastened to rectify it. This is as it should be," &c. Permit me to state that none of the observations made by me give the least foundation for such an assertion, and I now again reiterate what I before said.

Dissolving cannot be effected by alternately raising and lowering, by means of rackwork, the source of illumination; for, as soon as the light has left the first condenser in its passage to the other lantern, perfect darkness would result, and continue until the light reached the centre of the other optical system. This is the optical difficulty (not "optical error," as Mr. Martin styles it) which cannot be surmounted in a double lantern of the *perpendicular* arrangement. A contemporary periodical, alluding to this plan of dissolving, says:—"Such a method of dissolving must have been devised by one who was practically unacquainted with the lantern. He could not have used it successfully; and if he says otherwise, it clearly shows he has never tried it."

Regarding the sheer foolishness of such assertions as "my letting off the steam" and "pitching into the first person near me," which, unfortunately, happened to be Mr. Martin, such allusions could only emanate from the same source that recommended an attempt to "extract sunbeams from cucumbers," in order to obtain the honour of being the greatest benefactor to photography ever known.—Yours, &c.,
February 13th, 1871. SILVESTER.

PHOTO-MECHANICAL PRINTING.

DEAR SIR,—What have I done, that your correspondent "An Old Photographer" should be pleased to draw me into the controversies now pending on carbon printing, chemical and mechanical?

Any one reading the first paragraph on page 64 of your last number would imagine that the controversy in question was between myself and Mr. Edwards, when I have never had, nor never have, the least intention to enter on any controversy in the matter, being quite content to let my process stand on its own merits, good, bad, or indifferent.

The paragraph in question begins by your correspondent referring to the recent carbon discussions, and, after saying he is sick of it, he goes on to make a suggestion that Mr. Woodbury (*sic*) and Mr. Edwards should have a practical trial from the same negatives, to produce conviction. Now, what conclusion would any one reading the paragraph in question, and not having gone through the Johnson and Bovey, and Johnson Blair letters in a contemporary, come to? Why, that the whole carbon controversy was between Mr. Woodbury and Mr. Edwards. For Mr. Edwards I cannot speak, but for myself I may say that I know nothing whatever about the controversy, and do not wish to.

If any one wishes to acquaint himself as to the merits or demerits of my invention, let them visit the coming exhibition, where they will daily see my process worked in all its details.—I am, &c.,
WALTER B. WOODBURY.

CARBON V. SILVER.

SIR,—As the short and hurried note I sent you anent the carbon process was intended as a suggestion to yourself rather than for publication, I certainly shall not make any apology to Mr. Bovey for its want of courtesy.

His wilful blinking of the undoubted *facts* I stated with regard to the capability of the process to dodge defective negatives, and his poor attempt to pass them by as well-meant *suggestions*, the result of which would be more

troublesome than satisfactory, is so utterly beside the mark, that from any other person than one resolved to oppose the process at all hazards, I should have been surprised at it. As it is, I am content to leave him in the hot water in which he is at present, and trust that, like an over-exposed carbon print, he will emerge considerably improved.—Yours,
J. COOPER.

CARBON PRINTING V. SILVER PRINTING.

SIR,—Mr. Bovey appeals to me to deal with facts rather than phrases calculated to wound sensitive natures. It is to be regretted that he does not set an example; he, at least, never refrains from irritating epithets. I will, however, confine a few remarks I wish to make strictly to matters of fact.

In speaking of Mr. Edwards's heliotype process, I must again premise that I do not wish to use one deprecatory word. Within its *metier*, it is an admirable process, with, I hope, a great future before it. But I must repeat that Mr. Bovey evidently has a very imperfect knowledge of the process, or more probably, of the relation of the graphic arts generally, especially in connection with modes of printing. This is his misfortune; it is not a crime. The mode of pressure is really no essential element of any mode of printing. Of the three modes of pressure used in printing—vertical pressure for surface printing, scraping pressure for lithographic printing, and rolling pressure for copper-plate printing—each might be interchanged, and, I believe, is so occasionally. The mode commonly adopted for each is a matter of convenience, not of necessity. The kind of pressure giving best results is chosen. In the Alberttype class of processes, all kinds of pressure are used. Albert uses rolling pressure, Edwards vertical pressure, and in some, I believe, the ordinary lithographic press is employed. The mode of pressure does not constitute the *differentia*. In both the heliotype and the lithographic process the possibility of printing depends on the mutual repulsion of grease and water. This is the point in which the processes are alike, and in which they differ from surface printing, from copper-plate printing, from photographic printing, &c. From this fact the quality of the print must be similar in depth and richness. The lithograph differs from a copper-plate engraving in depth and richness, and in being more rotten in gradation, and in this the heliotype must be analogous to the lithograph. The necessity of using an intense ink to get force will interfere with transparency, and the necessity of using a transparent ink to get gradation will militate against depth.

On the question of the Woodbury prints Mr. Bovey is also seriously in error. A Woodbury print is composed of something more than gelatine and pigment, and a carbon print does not contain chromic acid. He is wrong on both points. All the chromic acid is removed from a carbon print in development and washing. The chrome salt which remains is a trace, nearly colourless, of sesquioxide of chromium in combination with the gelatine, rendering it insoluble. To test this, let Mr. Bovey produce a print with gelatine and bichromate, without any pigment at all, so that he may see what he is about. After washing in hot and cold water like a carbon print, he will find a faint greenish grey image, scarcely visible even in its deepest part; and this it is, and not chrome yellow, which remains in combination with the gelatine and pigment, the latter being so chosen as to quite neutralize it, a point which will be easily understood by artists in the habit of working with pigments. The Woodbury print is composed of gelatine, pigment, and a salt of aluminium, derived from the solution of alum used to render it insoluble. The one is rendered insoluble by a nearly colourless trace of a chrome salt, the other by an aluminium salt. Their identity is thus much nearer than Mr. Bovey has any notion of. Mr. Bovey is a good authority on the practice of silver printing; but no man is an authority on subjects with which he is not familiar.

To Mr. Edwards's courteous and intelligent letter I need only reply very briefly, as I agree with him in much. In so far as heliotype renders half-tone by gradation of flat tints, instead of a mechanical grain, it is superior to lithography. The capacity obtained by two inking operations is also of exceeding value; and if, as Mr. Edwards states, the intaglio character of the impression allows the depressions to be charged with ink, another point of importance would be gained. But, after all, it seems to me the very mode of inking the plate, in virtue of its lithographic analogy, must inevitably give it the lithographic

character; and everything I have yet seen produced by the heliotype, and all the varieties of the Lichtdruck process on the continent, have possessed this essentially lithographic character in the impressions.

In all that is said of the great value of the process for book illustration, for rapidity of production without reference to weather, for the possession of margin, and the absence of necessity for mounting, and a variety of other great advantages, I readily join in praise of heliotype. In its beauty and excellence as a photo-mechanical method I join in its praise not less readily. My exception was taken to the statement or implication that, for the purposes of the ordinary photographic portrait, heliotype was better suited than carbon, and gave more beautiful results.

With Mr. Edwards's remarks on the error of regarding silver printing as the standard of beauty or perfection I cordially agree. Notwithstanding certain beauties of gradation and richness of tone, most persons of cultured art taste regard an albuminized print as vulgar and inartistic, and, *pace* Mr. Bovey, would regard a good carbon print as a much higher class production, quite apart from the question of permanency. On the question of permanency in silver prints I have said nothing more, for, until Mr. Bovey or other photographers are prepared to issue silver prints with a guarantee of permanency, it is vain to defend the merely possible permanency of the results of the process.—Yours,
X. Y. Z.

[This controversy had better cease here. We have omitted the remarks in defence of a *nom de plume*, and on the supposition that Mr. Bovey declines the practical challenge, as unnecessary or offensive.—Ed.]

KEEPING SENSITIVE PAPER.

SIR,—In reply to "N.," I have much pleasure in offering to him the benefit of my experience.

Briefly: Atmospheric influences acting on free nitrate are the immediate causes of the discolouration of sensitive papers. If the paper, subsequent to sensitizing, is immersed in a weak aqueous gum solution, the thin coating of gum that is left after drying is capable of protecting the free nitrate for a considerable time.

Or, if preferred, the free nitrate might be converted into a chloride by immersing the sensitive paper in distilled water to which a few drops of hydrochloric acid have been added. Better still, alcohol (not methylated) might be used in lieu of water, as nitrate of silver is comparatively insoluble in the latter fluid.

There are other means of preserving sensitive papers which I should have pleasure to suggest to "N." on receipt of his address.—Yours truly,
W. T. BOVEY.

2, Charlton Villas, W.

ARITHMETICAL CURIOSITY.

DEAR SIR,—I know you cannot open your pages to all subjects; but having been a frequent contributor and one of your oldest readers, I cannot forego sending you a curious coincidence relative to dates which I discovered a few days since.

Starting with the hands of a clock at 0h 0m 0s, the minute hand during one hour passes over the several numbers 1, 2, 3,.....12; these being added together make the sum of 78, which, being multiplied by 24, the number of hours in the sidereal day, make the number 1872, or the date of next year. Of course this has never happened before in the Christian era, and never can happen again.—I am, sir, your obedient servant,
J. CARTER BROWNE, B.D.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

Address of the President.

At the recent annual meeting, the president addressed the members as follows:—

GENTLEMEN,—I must preface my remarks by thanking you for the honour you have done me in electing me to fill the presidential chair during the session on which we enter this evening, and by saying that my best efforts shall be given to advance the interests of our Society, and I trust that those efforts will meet with your kind approval. I may add that I trust to have the hearty co-operation of all members in rendering our monthly meetings interesting, and I hope that the year

before us may prove full of gratification to ourselves, and be one of progress for the art.

I believe I have to congratulate our members that our finances are in a satisfactory state, and in doing so would say that there are many amateur photographers in Liverpool and the neighbourhood whom we do not number amongst us, and whose names it is desirable that we should be able to add to the list of our members. Our pecuniary needs are not great, but I for one should like to see our numbers increased, and I our funds increased also. We do not require, perhaps, to prepare for a "rainy day," but there are many ways, I think, in which our Society might be benefitted if we accumulated some funds in the hands of our treasurer.

The year just closed has not been marked by any great advance in the art, though doubtless it has been one of steady progress. We have no great novelties to record, but the carbon and other processes have had the attention of some of the leading photographers, and have been perfected and brought into more general use.

As regards our own Society, I believe fewer papers have been read during the year than usual. It is perhaps only fair to state that other kindred societies have had to make the same complaint, and, therefore, we have not been singular in this respect. Considering, however, that we number amongst us some of the best and most practical amateurs, we cannot feel that we have not something wherewith to reproach ourselves in this matter. We are all working in various ways—probably no two of us in precisely the same groove—and we have each, I am sure, had under our notice subjects and ideas which would have been interesting to the general body if communicated to them. I will take leave to remind our members that, in a Society such as this, it is incumbent on each individual to do something for the good of the Society, and that no one of us can count himself a good and true member unless he can feel satisfied at the end of each year that he has done all he could during that year to add to the interest of our meetings. I would beg permission to be allowed to urge all to guard against that habit of thought which leads to the feeling that having paid the subscription for the year, and elected officers, it remains with the council, secretary, and president to provide for them an intellectual entertainment once a month, as well as tea and coffee.

Whilst in a consorial mood, you will perhaps allow me to say that I think we have not been quite wise in confining ourselves so exclusively to the collodio-bromide process. It is a most valuable process, and I do not wish for one moment to say anything otherwise than in praise of it; but I must express the opinion that we should not altogether give up the wet process for any dry process. We should, I think, work at both wet and dry processes, and not neglect the one for the other. Each is valuable to us at its proper time, and we cannot well do without either; but I put the question—Is it desirable that our members should confine themselves so exclusively to the practice of a dry process as they have done since the introduction of the collodio-bromide process?

I desire to draw the attention of our members to the good work being done in America by amateurs. I allude to the work of Dr. Woodward, of Washington, and Mr. Rutherford, of New York. The former has done more for microphotography than any other man, and the latter has taken pre-eminently the foremost place in making photography useful to astronomical science and research.

Dr. Woodward has certainly the advantage of holding a position as head of a government department, which has enabled him to spare neither time nor money in making successful the application of photography to microscopical science and investigation; but his work is essentially a labour of love, and he has the thanks of all interested in his particular line for all he has done, and for all the information he has so freely made public.

Mr. Rutherford has devoted himself to astro-photography, and freely spends his own money in the advancement of his art. His arrangements have hitherto been taken as a guide in the outfit of the different astronomical photographic expeditions, and his photographs of the moon and of the spectrum of the sun are said to be unique in the world. That of the spectrum of the sun shows more lines than the tables of Kirchhoff or Angstrom, and spectrum analysts are now engaged in experiments to determine what those new lines represent.

Mr. Rutherford has imposed upon himself the task of taking a photograph of the sun every day, and these successive pictures demonstrate most clearly the rotation of the sun. Spots

appearing on the eastern edge gradually cross the disc, disappear at the western edge, and in about twelve days appear again on the eastern edge.

Here is good work indeed, and in the labours of Dr. Woodward and Mr. Rutherford we see how valuable is the result of their steady painstaking. We have it plainly shown to us how much can be done by amateurs in work which professionals cannot undertake, by the steady pursuit of one object—by giving our work a definite purpose, and making all labour tend to the development of it.

It will occur to all of us that there is a great variety of work to be done by amateurs other than the taking of pretty views; and if we will lay down this rule for ourselves, that what we do shall have in it something useful and instructive as well as pleasing, we shall, I am sure, have the greatest pleasure in reviewing our work, and shall have the satisfaction of feeling that we are really promoting our art by rendering it in the fullest degree advantageous to others.

I would suggest that the building in which we are holding our meeting this evening is full of objects of interest of one kind or other, and that it would afford work for all of us for years to come. The ivories and the specimens of chinaware and glassware, from the earliest periods to the present time, would yield most interesting series. How valuable would be an ornithological series of photographs, not to mention more of the many subjects which our museum would yield us! We live in a town where every variety of naval architecture is, from time to time, seen; here, again, is a field of very interesting work. Engineering also affords us ample materials to work upon; and, as to architecture, it is a subject which can never be exhausted by us. A series of photographs of trees would yield us outdoor work, and would make an instructive portfolio. Photographs of a holiday trip are very interesting, an instance of which we had lately in the case of those shown us by the Rev. T. B. Banner, of many places visited by him last year, over which the desolating Franco-German war has since swept. How interesting might all our holiday trips become to us if we entered upon them with the purpose of adding to our portfolio photographs of the subject or subjects which we had set ourselves to illustrate! I think it must be admitted that we should do much more good by working with a definite purpose, than by possessing our cameras only as toys with which to amuse ourselves in our leisure hours.

We sometimes hear men say—"Oh! I have not done much this year; there are really so few pretty places within the reach of a few hours' journey!" One cannot help thinking, when this is said, that the person so expressing himself has a very small idea of the range of the art. We certainly ought not to look upon our art as a source of amusement only, but consider that it has much higher objects to fulfil.

I desire to take the present opportunity of offering some suggestions with the view of adding to the interest of our work and meetings.

I notice that, from time to time, we lose members, because they leave us for other countries, and the question naturally suggests itself—Why should these members be lost to us? Why should they not become honorary members? I think our Society would be benefitted if they continued to be associated with us. They might, I think, be entitled to receive a copy of the presentation print, and would, doubtless, from time to time, send us papers or communications of interest from the countries to which they had gone to reside, and our portfolios might be enriched with photographs taken by them in their adopted country. They might also, perhaps, compete in some of our sweepstakes, and for some of our prizes. If you agree with me in this, I would suggest such alterations or additions to our rules as will enable us to retain such members in future, even if we do not regain some already lost to us.

I beg also to suggest that we should have a fixed evening during each session when it shall be expected that every member will exhibit the work he has done during the year. I think the first meeting of each session would be a suitable evening for such an exhibition. It would be, I believe, instructive, and would act as an incentive to work during the year. And, in connection with this gathering, I should propose that each member give at least one photograph to be placed in a portfolio, which portfolio should be representative of the year's work. I would have a new portfolio every year, and would keep each year's photographs together, and separate from those produced in any other year. We should thus have a record of our yearly work, and these portfolios would indicate to us our progress.

Since I have been a member of this Society I have always felt wishful that an effort should be made to accumulate some funds, and that we should not be satisfied to collect what is barely sufficient for our present small expenditure.

I cannot but think it would be advantageous to have a room where our members could meet each other at any time and where plates might be prepared and developed, and where printing could be done. There are many periodicals published which might be taken in by us as a Society. Many members, I believe, could spare an hour in the daytime, and would have no objection to pay for a room where they could prepare and develop plates and print. It would probably be worth while to take the opinion of members on this subject at a subsequent meeting, and perhaps some of us would be prepared with a proposal which would elicit the general feeling.

Reverting again to the subject of papers for this session, I am glad to say that several members have already made promises, but we cannot look too much ahead; and, in order that we may not have to reproach ourselves in this respect another year, I hope that before we part this evening many more promises will be made. I have prepared a list of our meetings, and will pass this round, begging our members to enter their names for papers on some of the evenings. I must say I should like to see such a number promised as would render it necessary to take some of them as read, and print them for circulation. It is only what ought to be; and how would the interest of our meetings be increased if we had such a pressure of communications! We have an inexhaustible subject. We can never expect to arrive at perfection. We must always be going on perfecting our appliances, perfecting our processes, and accomplishing work previously unobtainable; and in all this there must necessarily arise a great deal which is of interest to the whole body of our members, and respecting which much would be gained by raising discussion, and obtaining the views, ideas, and suggestions of others. "Two heads are always better than one," and we may all learn something from each other. Let us not think that our processes and appliances are so good that we must have reached the goal of perfection.

Let us not rest on our oars, but, as we pass each turn of the stream of successful work accomplished, let us bend our shoulders to renewed exertions, determined to make all the progress possible whilst the day lasts us.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of this Society was held in the City of London College on the evening of Thursday, Feb. 9th, Mr SEBASTIAN DAVIS in the chair.

The minutes of a previous meeting having been read and confirmed,

Mr. E. DUNMORE read a paper 'On the Coming Season, and what shall we do in it?' (see p. 78).

After a vote of thanks, a desultory discussion took place.

Mr. C. E. ELLIOTT agreed with Mr. Dunmore that there was a growing demand for larger pictures by the public, as, being engaged in commerce in relation to photography, he was familiar with the fact that small photographs, however good, were little in demand. Pictures large enough to frame would sell best.

Mr. PRICE said that the idea of producing small pictures with a view to enlarging was important. But the small pictures must be exceedingly perfect, not only in sharpness of definition, but in those pictorial qualities which satisfied the eye. He thought the use of lenses of very short focus always gave a sense of untruth and falso perspective. Lenses of less than ten or twelve inches focus should not be used, except where circumstances made it imperative, as lenses of that focus produced pictures which at once seemed natural and pleasing.

Mr. WHARTON SIMPSON said it was a well-understood rule in optics, that to get the most truthful effect the picture should be viewed as nearly as possible at the same distance from the eyes as the lens had been from the sensitive surface; and, as the average focus of the eye would be ten or twelve inches, lenses of that focus gave the satisfactory results of which Mr. Price had spoken.

A desultory conversation followed on the enlargement of side objects when wide-angle lenses were used, and on the angle generally desirable to be included.

The CHAIRMAN said that the degree of sharpness of definition, and the distance at which a picture was intended to be examined, were important elements in the naturalness of a picture. One intended for examination in the hand must be much

sharper than one to be examined a few feet off. He thought the recognized rule, that a picture should be comprehended within a rectangle which could be cut out of a circle of 60°, was a good one.

Mr. PRICE thought a picture should represent a scene as the eyes see it, and the two eyes saw more than 60°; and, although the whole might not be sharp, the imagination filled up detail, and gave an effect to the mind of a more extended picture. A twelve-inch picture, with a lens of twelve inches focus, generally gave a satisfactory effect of both angle and perspective.

Mr. SIMPSON said that such a picture would include 60° on the diagonal, but not much more than 53° or 54° on the baseline.

A desultory conversation followed, in which Mr. Taylor, Mr. Dunmore, Mr. Price, Mr. Foxlee, Mr. Simpson, and the Chairman took part.

Mr. TAYLOR referred to the ingenious tourist's camera patented by Mr. Cook, which Mr. Elliott had promised to bring for the inspection of members next meeting. He also asked Mr. Price how he had found his clever camera work.

Mr. PRICE had taken about one hundred negatives, and was completely satisfied. He had used different lenses, having a fixed focus for each, and he found the definition perfect, bearing magnifying under a quarter object-glass. He also referred to the admirable action of perchloride of iron for cleaning and reducing negatives when used as recommended by Mr. Hughes.

A general conversation followed on enlargements, the use of curved plates, tissue negatives, &c., in which Mr. Foxlee, Mr. Dunmore, Mr. Price, the Chairman, and others took part.

Mr. PRICE promised to bring some of his negatives to next meeting, and give some details of the lenses and the conditions employed.

The proceedings then terminated.

THE PHOTOGRAPHIC SOCIETY OF LONDON.

The annual meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, February the 14th, Mr. J. GLAISHER, F.R.S., in the chair.

After the minutes of a previous meeting had been read and confirmed, Lord Lindsay was proposed and elected a member of the Society.

The CHAIRMAN called attention to some photographs of scenes in connection with the war, kindly sent by the Stereoscopic Company for the inspection of members, to some photographs by Sir Aubrey Paul, Bart., and to some examples of Manchester goods in the shape of cotton handkerchiefs in which photo-lithographic designs were printed.

The TREASURER then read a most satisfactory report, showing that the Society was in a very improving position. We shall refer to this subject in detail in our next.

The CHAIRMAN congratulated the Society on the improved aspect of their finances, and hoped at the next annual meeting to be able to announce that the Society was quite out of debt. He had felt deeply the position of the Society when he accepted the position of president, but he knew that with such a council they could not long remain in a position so unsatisfactory. He thanked all members for assistance, especially country members, and was glad to be able to promise that the Society would soon be in a position to do something more and better for its members than it had done heretofore. The £100 or £500 debt, under which they had struggled, gone, their prosperity would improve in every way.

The CHAIRMAN then read the report of the Council, which will appear in our next.

On the motion of Mr. Brooks, seconded by Mr. Bedford, the report of the treasurer and council were received and adopted.

The CHAIRMAN said that in the absence of Mr. Rejlander the consideration of the subject of splitting films would be postponed. This being an annual meeting, any member was at liberty to bring forward any questions he might wish considered. At the ordinary meetings he was bound in some degree to play the tyrant, and keep the proceedings to the matters set down. As no one seemed to have anything to propose, he should call on their secretary, who had kindly undertaken to fill the gap caused by the absence of Mr. Rejlander.

Mr. SPILLER gave an account of his experiments in the detection of fabrics, and the organic chloride formed by dissolving silk in hydrochloric acid, which gave a more sensitive chloride of silver than that usually obtained. He showed a series of elegant experiments and examples of fabrics treated, in illustration of the process.

The CHAIRMAN, in proposing a vote of thanks, commented on the value, as well as the ingenuity of the process, especially in superseding microscopic examinations by simple chemical tests. After the vote of thanks had been carried by acclamation.

Mr. THOMAS, at the invitation of the chairman, mentioned that the photographs exhibited by Sir Aubrey Paul, who was a professional photographer, had been taken in bad weather, some of them, interiors, having had as much as one and three-quarters of an hour exposure. A point of interest was the use of the ferridcyanide of potassium and persulphate of uranium for intensifying, used in successive solutions, with very careful washing between. Another point worth mentioning in his experience was getting good prints on paper which had been kept six months, the paper having been prepared on the bath of nitrates of silver and soda, with sugar added.

Mr. HUGHES referred to his experience as to negatives intensified with the ferridcyanide solution growing harder under the influence of light. They were beautifully delicate, and full of modelling at first, but gradually became hard and worthless during printing.

Mr. THOMAS said he believed that this was also Sir Aubrey's experience, but that an especially valuable power was thus in the hand of the photographer for reproductions in black-and-white, an example of which was shown.

After some conversation, the proceedings terminated.

Talk in the Studio.

OPERATORS' SPECIMENS.—The complaints of retention of specimens sent by operators desiring engagements, to employers advertising for assistants, still continues. We have suggested very efficient remedies, which are evidently not applied; but although the operator who fails to take the simple precautions we have suggested subjects himself to the risks often pointed out, it is not the less unjust of employers, where they are thus negligent in sending back specimens. Mr. J. Harris tells us of a case in which, having sent his specimens to a photographer in town, and failed to get them returned, he called to obtain them, and was curtly informed that the employer in question "did not return cards," and sent away without his specimens. If this were so, it was certainly unfair, if not dishonest. However, we can only refer to our former suggestions on the subject.

PORTRAIT NOVELTIES.—Mr. S. H. Jeffrycs sends us an example of card portraiture which is suggestive of various forms of novelty which ingenious portraitists may introduce to those of their customers desiring variation from the routine style of portraiture. This is a vignette portrait on what appears to be a scroll of white paper resting on a black ground. An ordinary vignette is apparently first produced, and then a mask representing the form of a half-rolled-up scroll of paper, being placed over the portrait, the edges are suffered to become black in the sun. After the print is finished, a few touches with a pencil and a little purple brown colour complete the effect of the scroll. Various designs of this kind are, of course, possible. Mr. Jeffrycs has styled this kind of portrait "the Effectograph."

ART WORKMAN'S EXHIBITION AT MANCHESTER.—A correspondent says:—"Perhaps photographers would like to know that their beautiful art was neither slighted nor contemned at the Art Workman's Exhibition just closed. I have just learnt that a silver medal has been awarded to A. F. Lafosse, Esq., of this city, for his excellent photograph at that Exhibition."

To Correspondents.

J. W. S. (Dewsbury).—We have much pleasure in aiding all classes of photographers with any advice in our power, our interest not being confined to either amateur or professional photographers. Do not hesitate, therefore, to write whenever you are "in a fix." Your desire to be able to take a first-rate photograph is a very proper ambition. Let us know in what points you fail, and we will endeavour to advise you as to the means of improvement.

H. HARDING.—Thanks for the correction. If the name occurs again we will see to its rectification. Thanks for the print and for the kind offer of use of negative. We had, however, selected a figure from nature.

F. GUY.—We presume that the Autotype Company print for the trade from photographers' own negatives. See their advertisement for address.

W. S. PARRY.—The letters have been forwarded.

AT A FIX.—As we are not in communication with the gentlemen whose formulae we quote, we cannot interpret their meaning with any certainty on doubtful points. The acetic acid chiefly in use in America is generally distinguished as No. 8, and is about equivalent to the acid generally known as Beaufoy's acetic acid. Glacial acetic acid is about three times the strength of this acid. A "small quantity" is a very arbitrary term, and must always be understood in relation to the subject. If we were making a developer by Mr. O'Neil's formula we should consider two ounces of acetic acid No. 8, or a third of that quantity of glacial acetic acid, a small quantity to add to the two ounces of iron dissolved in two quarts of water. 2. Alcohol plays no part in development; it is merely used to make the developer flow easily over the plate, and should never be used when it can be done without. We have not used it for many years. 3. Iodide of silver is made by adding a soluble iodide—such as iodide of potassium—to a solution of nitrate of silver, iodide of silver being precipitated. It is not necessary to add it to a nitrate bath in a direct form. Add from one to two grains of iodide of potassium to a pint of nitrate solution; this will form iodide of silver, which will be at once redissolved. 4. We have no special reason to think that the formula for developer giving twelve grains of protosulphate of iron to an ounce of water is a mistake. Some operators prefer a somewhat weak developer, in order that it may act slowly and gradually.

D. D. (Belgian subscriber).—We did not clearly understand your question, as the maker in question has several historical lenses without sufficiently distinctive terminology. Between the two lenses you name there is not much difference in rapidity; but as the one of longer focus (No. 1b) can be used with a larger aperture and still cover sufficiently, for rapid work it is, on the whole, preferable. If used with exactly the same relative aperture, the shorter focus (the four-and-a-half-inch) would be the more rapid. 2. In our experience, B is most rapid. 3. Two or three methods of oxidizing the last traces of hyposulphite of soda, and converting it into sulphate of soda, have been proposed. The use of peroxide of hydrogen has been tried, and doubtless answers the purpose, but it has never been extensively carried out. One part of oxygenated water, or peroxide of hydrogen, to ten parts of water will answer. A cheaper plan is to use a dilute solution of hypochlorite of soda, which answers a similar purpose. Theoretically the plan is good, and practically we have no reason to doubt it; but it has not been carried to sufficient extent, within our knowledge, to enable us to speak positively on the subject.

THE REV. S.—We will send you some numbers containing hints. Taking it altogether, the gum-gallic process is, we think, decidedly the best dry process in the balance of good qualities. Next, and perhaps simpler, is the coffee process, which yields admirable results. The use of a preliminary coating for gum-gallic plates is not an imperative condition; but, according to Mr. Gordon, the best authority on the subject, it is a very important condition. The backing with non-actinic colour is not imperative; for many subjects it is unnecessary, and with iron development less necessary than with alkaline development. Its use is to prevent halation or reflection from the back of the plate, which, when subjects containing strong contrasts are taken, is sometimes troublesome with plates which are not very opaque, such as those by the tannin process and the gum-gallic. 2. Tannin plates cannot be developed satisfactorily with iron. The tannin decomposes the iron solution at once, making black ink. The coffee process is as simple as and more efficient than the tannin.

J. BRYANT.—Many thanks.

BARRINGTON.—The cracks on the negative films which you have forwarded are of a kind which are only too common and too perplexing. These are of the kind we have generally described as vernicular; and if you have read all that we have written on the subject, we have, unfortunately, nothing to add. The cracks are clearly caused by contraction of the resins forming the film of varnish, and rigidity in the collodion film preventing it yielding, so as to contract in the same ratio as the varnish. In the negatives sent, the appearance is very suggestive of the fault belonging to the varnish. We can only suggest trying a fresh sample, or adopting the recent suggestion in our pages to add a little castor oil to the varnish. This, we think, is likely to be very efficient. A varnish made of gum-dammar dissolved in benzole will not be likely to crack, but it is not very hard. The varnish on the negatives sent is not hard, and still cracks. Rubbing fine lamp black into the cracks will make the negatives print without showing the cracks.

L. J. M.—As your letter is based on an assumption that Mr. Bovey shirks the trial, in which we think you are in error, and as it is unfairly personal, we regret that we cannot insert it. Good-humoured raillery is one thing, and bitter personal sarcasm another. The latter always stings, but rarely effects any other good end. Remember the Laureate's line to the effect that "mockery is the fume of little souls."

G. R. GILL.—Thanks. In our next.

JOSEPH STORES, BENE-VELIS, G. A. NICHOLSON, and several other Correspondents in our next.

A CURIOUS CAUSE OF DISTORTION IN PORTRAITS.

A SHORT time ago a very curious cause of inaccuracy or distortion in photographic portraits, and, indeed, in all photographic prints, was brought under our attention by our esteemed American correspondent, the details of which deserve more than a passing mention in his letter. He sent us two copies of a very charming cabinet portrait of a lady, by Mr. Baker, of Buffalo. It consists of the head and bust in an oval medallion, the head being about an inch and a-half long in the picture. The photography is very perfect, possessing exquisite delicacy and fine modelling, with perfect richness and brilliancy. The face is pleasant and intelligent, the features well cut, the eyes fine, the hair picturesque in arrangement, and the lace drapery is worn with graceful negligence. On examining the two portraits, a puzzled sensation takes possession of the observer: both pictures are apparently alike; they are posed alike, lighted precisely alike, and have the same character and contrast of light and shade; they are printed about the same depth, and touched to nearly the same colour; and yet there is a marked difference in the result. One portrait is infinitely more pleasing than the other. In one the face seems slightly more crisply cut, and has an exceedingly refined and spiritual air; the other, although pleasing, is decidedly heavier and more common-place in effect. Whilst we ourselves were puzzling over this discrepancy, a lady who had entered our study, and taken up the portraits, asked, with an exclamation of surprise, how it was possible that two photographic portraits, both so perfect as pictures, and so much alike, should so differ in refinement of feature and expression. And yet both these portraits are from one negative, which has not been touched or manipulated in any way between the printing of these two impressions; both printed the same day on pieces of paper cut from the same sheet; and both are fine silver prints with similar qualities of depth, tone, and brilliancy. The sole difference between the two consists in the different ratios of contraction of the paper under different circumstances.

The result of this difference in the degrees of contraction is singular, and by no means satisfactory to contemplate. On measurement, we find a very sensible difference in the proportions of the two faces. One is fully a twentieth part of an inch less in width than the other, the narrowest—that is, the one which has suffered the greatest amount of contraction in the width of the print—being, in this instance, the more pleasing of the two.

Mr. Baker explains that this difference in contraction results from the different modes of mounting employed. One print, he states, was mounted in the usual way, damp; the other was pasted, laid aside, and dried; then

the card was damped, the dried pasted surface laid on it, and passed under the roller. That which was coated with paste and mounted at once in the usual way suffered the least amount of contraction, whilst that which was coated with paste, and laid aside to dry, being mounted subsequently on the damped card, suffered the greater amount of contraction. In the individual instance under attention, the print which has contracted most, and, by its contraction, given increased crispness, at the same time making the face narrower, gives the most pleasing and refined likeness; but with many types precisely the opposite effect might be produced.

In many cases, however, the most truthful rendering of a subject would be preferable to the most pleasing, and hence the reader will inquire which of the prints approximates most to the truth in this case. We learn from Mr. Baker that here the print with the less amount of lateral contraction is that nearest to truth. In writing he remarks:—"You will immediately think that, as paper expands when damp, the dry mounted one must be the correct size. Not so, again; and comparative measurement with the negative shows that either head coincides with the impression on glass; indeed, the dry mounted print has contracted much more than the other has expanded. The print mounted in the customary way is the nearest right (assuming the negative to be truth)." This is a little puzzling. Let us glance for a moment at the action and reaction taking place. When the dry paper is first placed on the nitrate bath, it expands in proportion to the water absorbed, and contracts again when it has parted with that water and become dry, the excess of silver acquired not being sufficient to make any sensible difference in its bulk. It is printed when dry, and although it swells again when wet in the processes of toning, fixing, and washing, when dry it again contracts, and presumably possesses the same proportions as when it was printed in contact with the negative, so that the print should be an exact transcript of the negative. If it be pasted, and suffered to dry before mounting, the fair assumption would be that it still retains its original proportions, which would not be appreciably modified by being attached by pressure to a damp mount. When mounted in the ordinary manner, being moistened with paste, and swollen in consequence, and then mounted in contact with a comparatively unyielding piece of cardboard, contraction is to some extent checked, and it might naturally be concluded that the print would not acquire the exact proportions it had when printed. Mr. Baker finds, however, paradoxically enough, that although neither of the prints is precisely identical in proportion with the negative, yet that mounted in the usual manner, most likely to have been somewhat incorrect, is really the nearest to the truth, as represented in the negative.

But another very important fact remains to be taken into account in connection with this subject of expansion and contraction. If the contraction were equiform, each dimension diminishing in the same ratio, no distortion of the image could result; the size might be varied, but not the proportions. Unfortunately, this is not so, paper, like all textile fabrics, tending to contraction, after being wet, considerably more in one dimension than in another. This fact has before been pointed out to photographers, but is less known generally than it should be. Mr. Baker finds that the contraction in the narrow direction of the sheet is nearly three times as great as in the direction of the length. Whether both the prints were on pieces of paper cut in the same direction of the sheet is not stated; but as Mr. Baker, fully alive to all the facts, attributes the difference to the mounting only, we presume that they were. Here, then, is a startling source of error, which must be, more or less, that of all photographs on paper.

Mr. Baker observes:—"This is an important, constantly present, and, it seems to me, unavoidable cause of photographic distortion. Let both of these heads be magnified to life size, in length, from the outer right-hand corner of the mouth to the inner corner of the right eye, $2\frac{1}{4}$ inches, and the divergence in width would become comparatively enormous. Let now the head be carefully traced by the hand, following the solar camera image of the negative, and a third scale of dimensions is produced. Print from the negative, in a solar camera, with the length of the paper placed across the width of the face; then another print, with paper placed with its length parallel to the length of the face, and you have a fourth and fifth scale; under all conceivable conditions this cause of distortion remains."

Mr. Baker very justly adds:—"So, then, photography, usually conceived of as being perfectly literal and true, is found in many ways to be inexact; and here, as in other studies, the conviction is forced upon us that man has not absolute truth, only adumbrations thereof. In several instances this property of the paper has proved quite vexatious to me, when absolutely correct copies were wanted for mathematical purposes. A plan that was to be just 11 inches long, and was so on the negative, came out about $11\frac{1}{2}$ inches on the mounted proof. A medallion which was to be copied to a certain oval, the pattern of which was furnished, was carefully prepared on the negative, but the oval on the finished print was swelled in the width out of all proportion; so much so, that the maker of the marble would not believe it possible that the negative had been properly treated, until it was shown him, and he laid the pattern on it himself."

The photographer has generally been in the habit of regarding imperfections in his lenses as the only source of distortion or error in proportion possible in his delineations, and a lens convicted of destroying the proportion of a face, or of any design, to the extent of at least one-twentieth of one of its dimensions, would seriously peril the reputation of its maker. But here is a source of error apparently inevitable. The photographer may take heart of grace, however, when he remembers that not alone photographs, but every form of picture on paper, is subject, in greater or less degree, to the same conditions, if it have to be mounted, and that hence the defect is not one peculiar to photography, but simply incident to delineations on paper, whenever that paper is subject to the process of dampening and drying, after it has received its design, and perhaps in no case is the liability to this distortion greater than in the tracings of the engineer, where mathematical accuracy is often of vital importance. Mr. Baker adds:—"Yet we may comfort ourselves, that in the case of portraiture it must be a wonderfully accurate eye that could detect the variations as compared with the living model, and even then it would be a decided hypercriticism to find fault with drawing; that is, if necessarily somewhat at fault, yet far more accurate than handwork."

It should be remembered, however, that in the examples upon which these remarks have been based, the variation is sufficiently palpable to excite attention, and to make all the difference to which we have referred in the delicacy and refinement of effect. One of the best uses to which a knowledge of this peculiarity in paper could be put would be careful consideration of the peculiarities of a face, and whether its appearance would be improved by contraction in width or length. The effect of a broad, coarse face might be ameliorated and refined by a slight contraction in width; a long, lean, haggard face, by being slightly diminished in length. The range of artistic power in making the best of his subject may be enlarged by a consideration of these facts, and cutting the paper for a portrait the lengthwise or breadthwise of the sheet. If this were always judiciously done, a defect and shortcoming might be converted into a new power, frequently giving a more pleasing quality to photographic portraiture.

MODIFIED PRINTING FORMULAS.

BY E. AND H. T. ANTHONY.

IN consequence of the improved modes of working discovered and introduced by ourselves, the process of printing and toning albuminized paper has been greatly facilitated and cheapened.

The old mode of working was as follows:—

A solution of nitrate of silver was made, 50 grains to the ounce of water; this was neutralized by the addition of a little ammonia, the precipitate allowed to settle, and the clear solution decanted. The paper was floated one minute, hung up to dry, and fumed fifteen to twenty minutes with ammonia.

After printing, the prints were thoroughly washed, and toned in an alkaline gold bath.

The new mode is as follows:—

The silver solution is prepared with ammonia as formerly, but is made only 35 grains to the ounce of water. After the clear solution is poured off, it is saturated with powdered alum. The paper is floated one minute, and dried. It can now be used either with or without fuming with ammonia. If the ammonia be used, five minutes' exposure to the vapour is long enough; if the ammonia be not used, the acid wash before toning may be omitted.

After printing, the prints are soaked ten or fifteen minutes in a solution of pure acetic acid No. 8—say one drachm to a quart and a half of water. They are subsequently rinsed in two changes of water, and are then ready for the toning bath. Prints treated in the above manner require very little gold for toning.

It is very easy to make a toning bath if the chloride of gold solution be first neutralized by means of an insoluble alkali. To do this, make a solution of 15 grains of Anthony's chloride of gold in one ounce of water; put in 10 grains of carbonate of baryta, and allow the mixture to stand two or three days, with occasional shaking. The carbonate of baryta destroys the acidity of the gold without being dissolved in the water. All that is necessary to do now is, to add some of your neutralized gold to water, put in a little salt (say 30 grains to a quart of water), and a very little of any of the alkaline salts used in toning.

According to the depth of the toning will be the resulting colour of the print: a lightly toned print being a pleasant brown, while those very deeply toned become purplish blue.

By washing the prints in water first, and subsequently soaking them in a very weak solution of salt, with very light toning, a chestnut brown can be obtained.

Fix in fresh hypo solution—one of hypo to eight of water—and wash three hours in running water, occasionally drawing off all the water, and allowing the prints to drain well.—*Photographic Bulletin.*

AMERICAN CORRESPONDENCE.

REMBRANDT PICTURES, AND HOW TO PRODUCE THEM.

Rembrandt Pictures, and How to Produce Them.—You have had a great deal to say about our American "shadow" pictures, and have republished a great deal that has been said here about them. With us they are generally called Rembrandt pictures, not so much because they are presumed to be like the works of that famous Dutchman, but simply to give them a "taking" name. For the same reason we dub our new size Victoria cartes, not because they are like the cartes made by your good Queen, or her princely amateur son; neither because it is supposed that your excellent Sovereign prefers to have her portraits for Eugenie and others taken of that particular size, but simply to give them an attractive name, one that will be remembered easily, and create enquiry for them.

Let us, then, call the pictures in question Rembrandts. How wild, indeed, would Rembrandt be could he see what wild lighting is practised by some of our good people here in trying to secure striking effects! But there is a good way of making very attractive and excellent pictures a little different from the ordinary run, and a few remarks on their production may not be out of place.

In this country the majority of the *ateliers* have a north top exposure—i.e. the top light inclines to the north—and an east and west or an east or west side light. Here, then, is the method of making Rembrandts in such a studio:—

A is the operating room, B the skylight, C side light, *a* sitter, *e* camera, *f* background. For Rembrandts the background should not be too dark; many make a mistake in using a very dark one. An amber tint, or something a shade lighter, does well. *g* a semi-opaque screen, hinged to, or placed against, the end of the background. This is for the purpose of making that side of the ground darker. It accomplishes, in some measure, what is produced by a cone or curved background. If you want something expensive, you can buy some one of the several patterns that are in the market; or there is a good description of how to make an "alcove ground," with a diagram, in a late number of the PHOTOGRAPHIC NEWS. But I want to give you something that you can use or find in any gallery. If it is desirable to have the ground lighter on that side, leave the screen away; but it is rather more artistic to give the ground a darker shade on the side nearest the light. *h* is a screen with a joint in the middle, or two separate screens, covered with white muslin, to use as reflectors; *i* is a screen with one side a light colour, and the other a sort of neutral tint. These are the arrangements for Rembrandts, showing the left side of the face; and, when you want the right side, make the same arrangements on the other side of the skylight. For ordinary sittings the camera is at *j*, the sitter at *k*, background *l*, and side-screens *m*; and *vice versa* for the other side of the face. Under a differently constructed skylight you might be obliged to make some variation from this arrangement, but, with a little care and judgment, it can be applied under any light. They are a picture not easy to make well, but one can soon learn. If one has acquired the faculty of seeing the light on the face of the subject, instead of trusting to the focusing glass to tell him when it is right, then the work is comparatively easy. Let me give you a couple of examples, and then I will close on this subject:—

Enter a lady with a fine profile—the latter you see at once, even before you can tell what the lady looks like. In the first place find which side she is to sit, and arrange the light accordingly. Bring the background up near the side light, and place the screen so as to shade a portion of the background nearest the light. Place the sitter well forward, so as not to be back of the light, and carry the screen round on the shadow side, so as to give a good diffusion of light. Don't get the reflecting-screen too near to cut off too much of the shadow. The camera should stand pointing well towards the light. Let the body be turned a very little from the front, and then the head inclined gracefully to the right till the profile is presented to the camera. That brings the front of the face against the shaded part of the background, so that we get the highest lights of the face against the darkest part of the ground. Now the next point to be considered is, the regulating of the light. Draw down the thin curtains on the top light till the direct light comes only from the lower side; now soften the side light till we get the effect we want. You see, by cutting off the direct light from above, and letting the principal rays come from the side light, the side of the face next the camera is entirely in shadow, while the other is brilliantly illuminated.

The next subject is a gentleman. His face will look best with about a three-quarter view. This requires very careful management of the light. A view that just catches the line of the nose is favourable, if it does well for the general outline of the head and face. If more of a side view is necessary, care must be taken not to have the cheek and nose illuminated the same, or they will run together, and the shape of that very important feature the nose will not be defined. Turning the subject a little more to the right, so that the strongest illumination will be partly from behind, will throw the front of the cheek a little in shadow, while the nose, catching the full light, will be well defined. A dark complexion will not bear so much shadow as a light one. Care must be taken in this view to get no reflections in the eyes from the screens. It is well to have the screen behind the camera darker on one side—a gray or dark blue, that will give a neutral tint—so that it can be turned when desired. There is a satisfaction in doing this kind of work when you have subjects suitable for it. But it is surprising how quickly people have caught the idea that a Rembrandt will make the plainest face brilliant and beautiful. I believe they are better posted on the characteristics of Rembrandt's style than we have given them credit for.

The unfortunate ones that "never had a good picture" are all out after the new style. The old, gray, and wrinkled want to try something that will, perchance, restore to them the force and vigour of former years, and smooth the furrows that time has wrought on their brows. The young lady, who has been a young lady for many years, and has never passed a certain age, whose mirror has grown old, and is not as true as it used to be, comes to try a Rembrandt, hoping to have the hollows in her cheeks filled up, and the winning grace and beauty she has so long sighed for restored by its magic touch. When skillfully and carefully made, they are certainly very pretty, and no doubt are an old thing to some of your readers.—Yours truly,

EDWARD L. WILSON.

Philadelphia, February 1st, 1871.

ON A CONVENIENT WAY OF PREPARING COLLODIO-CHLORIDE.

BY P. LIESEGANG, PH.D., A.M.

To prepare a good sample of collodio-chloride is not at all difficult, after the large number of good formulæ which have been published; and I should not burden the photographic community with another one if I had not had a long experience with it, having prepared a few hundred of pounds of collodio-chloride in this way.

I find that the shortest way is to dissolve the chloride in plain collodion, to add the nitrate in such pieces as it is

bought, to shake the mixture well for a time, and then to add the acid. Not a trace of water is thus introduced into the collodion, no difficulty in dissolving the nitrate in strong alcohol. The best plain collodion for this process is one in which equal parts of soluble cotton and papyroxylene have been dissolved. I use the following proportions:—

Alcohol, absolute	1 fl. oz.
Ether O 725	1 "
Papyroxylene	9 grains
Soluble cotton	9 "

This collodion is cleared in the usual way, by filtering, if it must be used at once, or, better, by keeping and decanting it.

The sensitive collodion I compose of—

Collodion, as above	1 oz. fl.
Chloride of lithium	1 grain
Nitrate of silver	8 grains
Citric or tartaric acid	2 "

I dissolve the chloride of lithium in clear collodion, then add the nitrate of silver. We have here very convenient bottles at hand for preparing the collodio-chloride, those in which the Moselle is sold; they are of a yellowish-brown, just clear enough to allow the eye to follow the formation of the sensitive salt, and yet obstructing all chemical action of the light. The collodion is shaken until it has become milk-white; next day it is poured in another bottle, leaving the undissolved pieces of nitrate behind. These are now powdered in a mortar, and well mixed with the collodion.

The two grains of acid are then dissolved in the collodion, which is now ready for use, or will keep for months.

If the collodion is to be used for reproducing negatives or printing lantern transparencies, a few drops of a solution of shellac in liquor Ozonii (alcohol saturated with ammonia gas) are mixed with it just before use, as the mixture will not decompose on keeping. The deepest black can be obtained thus without pyro developing.

Also, by coating twice with the above collodion (without shellac), very deep tones are obtained.

Where good chloride of lithium is not to be had, I recommend the following formula:—

Plain collodion	1 fl. oz.
Chloride of cadmium	2 grains
Nitrate of silver	8 "
Citric acid	3 "

To prepare in the same way as indicated above.

PAPER NEGATIVE PROCESS.

BY WM. BLAIR.

FURTHER experience enables to make one or two additions to the remarks I formerly published on this process.

After a variety of trials with india-rubber paper, I found that I succeeded best with some very old prepared paper that I had had lying past for some years, but that with paper newly prepared it was difficult to avoid stains, especially with silver development, if the sensitized sheet was kept over a few days. This might all be avoided, no doubt, by thoroughly pure solvents being used for the rubber varnish, and evaporating completely before using, and adopting the additional precaution of coating with albumen. Rubber solution has often been used as a coating for glass, and there is no reason why, if properly prepared, it should not answer on paper. Still, I have to admit that the materials recently obtained by me, and used in these trials, did not fulfil expectations, and this has induced me, in the meantime, to fall back upon waxed paper.

I am not sure, indeed, but that waxed paper may turn out to be the superior article for this process after all. Wax is a cleanly neutral body, and has been proved long ago to be very useful in the silver process-s. I have tried some collodion negatives on waxed paper by the process

referred to, and find that they develop quite clean, and are easily separated from the waxed sheet.

I take a piece of waxed paper of convenient size; flatten it down on a sheet of glass, spread dilute albumen over it with a bent glass rod, pour off, and hang up to dry spontaneously. When dry, flatten again, and pour the collodion on the albuminized side. The albumen prevents the collodion from attacking and dissolving the wax. A thin coating of gelatine may serve the same purpose. I would recommend the use of collodio-bromide for these paper processes, but otherwise the film can be sensitized by floating on a bath as formerly mentioned. When well washed, and the preservative applied, the sheet should again be hung up (in the dark) to dry spontaneously. Any attempt to hasten the drying by heat would be apt to start the collodion from the wax. All artificial heat should be avoided till the finished and gelatinized negative is to be lifted from the paper, and even then I find it can be taken away without any extra application of heat.

As, in this process, the collodion has a comparatively weak hold of the paper, I think it will be found a safe precaution to run a small edging of rubber solution round the border of the paper before sensitizing. This border may, perhaps, be better cut away after the negative is finished and the gelatine dry, so as to get the waxed paper more conveniently separated. A sheet of waxed paper, unless cut down into very small slips for small negatives, may be used oftener than once for this process.

After the picture is developed and fixed, and while still wet, the warm gelatine should be poured on to as great a depth as it will conveniently carry without running over. When set, it is hung to dry in a good current of air, if such can be had.

The film negative obtained in this way has much the appearance of a negative on ground glass. The slight roughness of the surface of the paper seems to communicate to the gelatine that appearance, but the dead surface thus communicated answers very well for working on with the pencil, if that should be considered necessary or desirable.

I have met with one difficulty in this process which it is right I should mention. During these short winter days I have only developed after dark with a screened lamp, and on applying the fixing solution I find great difficulty in knowing when the yellow iodide and bromide are sufficiently cleared away. With a glass negative there is not much difficulty here, but with these films resting on white paper the disappearance of the yellow colour is not so easily observed, and I have often found, on afterwards examining the films in daylight, that they had been imperfectly fixed. This is a difficulty, of course, that will only occur in developing and fixing by night light, and may be got over by experience and a correct knowledge of the strength of the solution used.

Bridgend, Perth, February, 1871.

EXPERIMENTS WITH WASHED CHLORIDE OF SILVER PAPER.

BY C. ENGELMANN.*

AFTER some experience, I have found it best to wash the sensitized paper, in the first place, in two baths of distilled water, and subsequently in good spring water; or, if none of good quality is at hand, with distilled water, to which a minute quantity of bicarbonate of potash or common salt has been added.

In this way a paper is obtained in which all free nitrate of silver has been completely removed, and which, therefore, may be preserved in good condition for a considerable period. When exposed to full daylight, it assumes a light brown tone, and cannot be used for printing purposes without the aid of ammonia fuming. If exposed, during the operation of printing, to the action of ammonia, the

* *Helios.*

latter acts upon the chloride, and pictures are then produced hardly to be distinguished from those printed in the ordinary manner, the printing being conducted very rapidly. The ammonia reaches the paper through the medium of the printing pads, which are placed in a box together with a saucer containing strong spirits of ammonia. Over the vessel is placed a false bottom of perforated cardboard, and upon this the pads are allowed to remain for twenty-four hours before employment in the frame. The ammonia used should be as strong as possible, especially if the albuminized paper has been sensitized upon a weak silver bath.

A most peculiar fact is here apparent. One would surely believe that the concentration of the silver bath would be of but little importance, inasmuch as not more nor less chloride of silver can be formed in the paper than there is salt contained therein; and yet this strength of the bath does influence the result very materially. At any rate, with a concentrated solution, a finer and more easily decomposed chloride is formed, than when a liquid of less strength is employed; and, in fact, a proof of this is found in ordinary working, when, in using a bath until almost exhausted, we reach a point when a dusty kind of chloride is formed, so difficultly decomposed by light that we condemn such paper as altogether useless. It can scarcely be said that free nitrate of silver is here absent, and, if the paper is again floated upon a second and stronger solution, no improvement in its printing qualities is to be observed.

On the other hand, a more sensitive paper is obtained than that yielded by a weak bath, if the sheet is, in the first instance, floated upon a strong solution, and afterwards placed in a dilute silver liquid, where it is, to a certain extent, again washed.

The fuming of the paper itself with ammonia without having recourse to the pad will not answer, inasmuch as the sheets do not of themselves absorb a sufficient quantity of the compound; on the other hand, too much ammonia need not be feared.

As regards the advantages of employing this paper, the principal one lies in the fact of the superior keeping qualities of the sensitized material, some paper which I have prepared in February being still good in the month of May. This preservative quality is an important one, for it is then possible to rely upon a large batch of prints in early morning; while in bad weather, when little printing can be done, one is not left with a large batch of sensitive paper on hand, which will rapidly deteriorate. This advantage alone, then, leads one to hope for the perfect elaboration of the process.

The results I obtained on a small scale were such as to decide me in adopting the method upon a large scale for ordinary photographic printing, although for vignettes it was scarcely suitable, owing to a yellow or reddish halo which formed round pictures of this description. But, alas! after four weeks' work, I was compelled to return to my old way of proceeding, for I found, practically, that for large printing operations it was unsatisfactory. Mistakes amongst the work people were frequent, the pads being sometimes used twice over, or the replenishing of the ammonia in the box forgotten; in short, without everything was done personally, it was impossible to make matters go on smoothly, for, as we know, one can never get assistants to feel the same interest in the matter as oneself. Should, from one cause or another, the pad be too thinly saturated with ammonia, the prints may possibly assume the same vigorous character as when sufficient ammonia is present; but they always lose much of their brilliancy when placed in the hyposulphite fixing bath. The silver solution employed by me was prepared in the proportion of one to twelve, as I found that one of less strength did not give satisfactory results.

The method would be more reliable if the ammonia were not volatile, or if it were actually in chemical combination with the chloride of silver.

THE INTERNATIONAL EXHIBITION OF 1871.

BY THEOPHILUS THIDDLEMIDTCH.

No. 1.—How I Took My Pictures.

MANY months ago there appeared in one of the daily papers, and in a very obscure corner thereof, an advertisement in very small type, which set forth, to those who wished for such information—or, rather, to those who had the luck to find it—that Her Most Gracious Majesty's Royal Commissioners "would accept a few photographs for their exhibition." It was very kind of the Commission to say they would allow a few photographs to be exhibited, and it was still more considerate of them to announce the fact in a public advertisement. While it would have been simply impossible for these favours to have been surpassed, they were fully equalled by a most generous desire *not to make the thing too common*, so that the little advertisement I have referred to was confined to one paper, and to one insertion.

It would be an interesting subject for a Royal Commission to enquire into and report upon the number and nature of the answers which this advertisement received. For my own part, I wrote next day a laconic note, saying that it was "my intention" to exhibit a collection of photographs, and asking for a space of about a hundred square feet. In about three weeks I received an answer "done" in the most official manner, and stating that my letter had been duly received.

Months now passed by, and nothing more was heard of the exhibition; when, in December, thinking that the frames I intended for exhibition should be prepared, I wrote again to the "Royal Commission," to ask if they intended to allot a space equal to the magnitude of my desire.

To this letter I received an answer to the effect that I should have no space at all allotted to me, but that I might send them any pictures I liked, to choose from, and they would, perhaps, hang a few!

This seemed to me to be only an "official" way of explaining that indifferent muffs would be kept out, and that thereby a much larger space would really be allotted to those who were ready with plenty of good pictures, and I therefore set to work to get up some forty or more of the best pictures in my collection.

In about a month I received another letter from the "Commission," containing several different sorts of labels, and a request that I would write and ask for as many as I required. I modestly said to myself, "Of course, they cannot think of refusing, so I will send for a good batch." I accordingly wrote for fifty of each.

In a week I received, by way of answer to my application, a letter containing twelve labels, and a memorandum stating that, as it was very improbable that the "Committee of Selection" would put more than three or four of my pictures into the exhibition, I might satisfy myself to send only the best of what I had prepared. I read this as a challenge—I read this letter as an insult. It must have been an insult to suppose that a photographer of my standing could only do *four* pictures fit to look at! What could I do? Should I write and say I would not exhibit at all? I had a mind to, but I thought I would first try the effect of one of *my* letters; so I wrote that, "so far as I was concerned personally, I didn't care a pin for their exhibition; that they might all go to—; that I exhibited for the public, and not for myself; that I felt it was a duty incumbent upon me to teach the *nations* by an example or two from *my* studio; that the public expected it; that the Editor of the PHOTOGRAPHIC NEWS expected it; that England expected it!"

This fetched them. By return of post an enormous parcel of papers, forms, and labels were delivered to me; and, as I exultingly carried them to my studio, I could not help feeling, mingled with my pride, a touch of sorrow at the vast expense I had incurred upon the Commission in printing and stationery.

I pass over weeks. The fatal day arrived. I refer to a "fatal day," because, by an advertisement which had been inserted at the last moment, in a great many papers, the 21st February, 1871, was fixed as the only day for sending in—or, rather, taking in—the few photographs which were to be exhibited.

I presented myself at the doors of that wonderful "oval circus," as the cabman called it—irreverent cabman!—and was most politely assisted at once by about half-a-dozen intelligent fellows, who seemed as if they enjoyed the job quite as much as sponging guns or "position drill." I was forthwith ushered upstairs into the presence of two or three secretaries, who were looking over other exhibits, and doing to others as they did to me. "Take off those labels," said the first secretary, advancing to me; "you have made them out wrong." "What could have made you fasten the labels on the backs of the pictures?" said the second secretary. "They are too ugly to go on the front," I said. Whereat he laughed, and was very civil all the rest of the morning, for I must tell you that these gentlemen made me write out the whole of my labels again, notwithstanding that I had made them out with the greatest care, according to their printed direction. In fact, one of them (you may have seen it, a great ugly square thing with printing on it in red), I had done in a style which would, I am sure, have been a credit to any catalogue. I was not, it is true, at all clear about the "class number," but then, that was a matter more exclusively official than my attainments could arrive at. The "nature and title of the subject," and, in most cases, the date of production and price, I could fill in with pride, if not with accuracy. "My name" is well known, but the "date and place of my birth!"—Sir, this is a sacred particular, which I should not have felt justified in revealing, had it not been for the inestimable advantage of the information to my own and future ages. Fortunately, from a very accurate record kept by my father, I was able to indicate, not only the town, street, house, but even the room, in which the momentous event took place. The time was recorded with astronomical precision. I cannot say I was equally clear in stating the "school of art at which I studied." But when it came to describing the honours which I had obtained, it almost takes my breath away. I had a separate list printed, and pinned it on to each. I omitted to fill in the column for "any other information," not knowing if it referred to measles or my twin-brother.

Sir, you, and you only, who know me well, can judge of the indignation with which I saw my labels torn up, and my separate list of honours destroyed as unworthy a place in the catalogue of so vast and magnificent an exhibition.

It took me three hours to write out the lists and labels again, and during all the time I was so occupied, not one came into the room but had to make some alteration, or to do the same as I had, and write their papers all over again.

There promises to be an exceedingly fine collection of photographs at the exhibition, as there was one frame delivered in the three hours of my attendance.

PHOTOGRAPHS OF GAOL-BIRDS.*

THE recent refusal of certain prisoners committed for trial at Liverpool to submit to the operations of the gaol photographer suggests some important considerations in reference to the working of the Habitual Criminals Act, and its powers in relation to the identification of persons charged with crime. Prison portraiture is not altogether a novelty. When Mr. Pickwick entered the Fleet, the first ceremony through which he passed consisted in "sitting for his portrait," the warders being, as he was informed by the stout turnkey, "capital hands at likenesses, taking 'em in no time, and always exact." The substitution of photography

* From the *Morning Advertiser*.

for the more embarrassing process of personal scrutiny by half a dozen turnkeys would scarcely appear to be a hardship, unless some more occult reason than appears on the surface exists for objection to the record of the camera. Oliver Wendell Holmes, in one of his delightful essays, affects to discover in photography an explanation of the classic fable, which relates the slaying of Marsyas by Apollo, after the young shepherd had been beaten in a musical contest with the god of music. Mr. Holmes suggests that as the god of song is also the god of light, the slaying consisted in fastening his victim to a tree—symbol of a modern photographer's instrument of torture—and taking a sun portrait of him, the thin film or skin of light and shade projected direct from his body to the sensitive tablet having been by uninstructed persons interpreted as the *cutis* of the defeated minstrel. If the photographed prisoner takes this view, and feels a sense of loss, of virtue gone out of him, during the moments in which the Cyclopean eye of the camera is fixed upon him, it is not surprising that he objects to the process; or, what is still more probable, if he be conscious that the evidence against him may be strengthened tenfold by his identification leading to the record of former convictions, his personal objection may be easily understood. The ground upon which this objection is endorsed, and "torture by photography" denounced by sham humanitarians, is not so clear. In order fairly to estimate the value of the system, a glance at its history may not be uninteresting.

The idea of preserving a photographic record of the prisoners under his charge, with a view to subsequent identification, is due to Mr. J. A. Gardiner, governor of Bristol gaol. About fifteen years ago he addressed a letter to the governors of Her Majesty's gaols generally, pointing out the importance of such a record. "It is well known to all," he said, "who have been concerned in criminal administration, that the most cunning, the most skilled, and the most daring offenders are migratory in their habits; that they do not locate themselves in any particular town or district, but extend their ravages to wherever there is the most open field for crime;" the best planned robberies, he adds, being rarely conducted by the resident thieves in any district. As an issue of this migratory tendency, it was found that convicts were constantly returning to prison for short terms in fresh districts; expert professional thieves, experienced and hardened criminals, being enabled to pass off lightly as first offenders only just trembling on the verge of crime. In the exact ratio in which criminals were brought within fresh judicial districts, and under fresh official inspection, the chances of identification became diminished; written descriptions rarely being sufficiently special or characteristic to fix identity with any certainty. Hence Mr. Gardiner was induced to try photography, and to recommend its general adoption. The success which attended the partial application of the system induced a Select Committee of the House of Lords, on whose report the Prison Act of 1865 was framed, to recommend its universal adoption in Her Majesty's prisons, regarding it as "inexpensive, effective, and wholly free from objection." The system was only partially applied, however, until twelve months ago, when, by order of the Home Secretary, its application became more general. The plan pursued is simple and efficient. As soon as the prisoner arrives in gaol he is photographed, and copies of his portrait, attached to a schedule describing his age, height, complexion, hair, eyes, nose, whiskers, and specific marks, together with such details of his place of birth, education, trade, religion, and place of residence as he chooses to communicate, are sent to the governors of other gaols, stating that the prisoner is in custody for trial, and requesting that if he be recognized as having been in custody before, details of his convictions may be furnished. In many gaols all prisoners are photographed but the general application of the system is only made imperative in relation to the classes specially noted in the Habitual Criminals Act, the aim being to secure a record, with means

of identification, of all professional thieves or persons in the habitual practice of crime.

This system—which, in the excellence of its aim, is beyond question, and the success of which, even in partial application, has, according to the evidence of the governors of various gaols, far transcended expectation—is in danger from a somewhat singular cause. A few of the prisoners object to be photographed; and at Liverpool, where two prisoners committed for trial have recently refused to sit before the prison camera, the visiting justices have resolved to communicate with the Home Secretary to suggest that the photographic portraiture of prisoners shall in all cases be compulsory, and refusal to submit to it followed by punishment. There is little hope of aid for the justices, we fear, from a Home Secretary who has shown his country so many instances of weakness and vacillation, and who suffered his ridiculous cab law to be ignored with contempt because cab proprietors and cab drivers very naturally objected to its preposterous conditions. Fortunately for the appeal of the visiting justices, Mr. Bruce is, in this instance, called upon to exceed his powers, and the opportunity for the arbitrary disregard of an Act of Parliament may afford him some temptation. The section of the Habitual Criminals Act which provides for the preservation of a record of criminals, with means of identifying them, specifically refers to persons "convicted of crime." Such persons are also, according to the statute, to be subject to the regulations which may from time to time be prescribed by one of Her Majesty's Secretaries of State. But, so far as compulsory photography is concerned, persons merely charged with crime, and awaiting their trial, are not amenable to either force or punishment. But this fact need not impede the carrying out of a valuable system. In its partial application neither force nor punishment has been necessary. In the instances where consent has been refused, contumacy has been met by contrivance, and the portrait has been secured, at times without the knowledge of the sitter, without imperilling the liberty of the subject. If the preservation of a minute written description of a person charged with crime be legitimate, the less elaborate, but more accurate, record of the camera—which, if it nothing extenuate, will set down nought in malice—needs neither the authority of the Home Secretary nor an Act of Parliament to justify its preservation.

A system which aids in placing on record an accurate register of all professional law-breakers, and in doing so preserves a distinction between the unfortunate and the vicious, between the confirmed criminal and the fledgling goal-bird, needs no platitudes on the sacredness of society, nor on the powers of science in tracking crime, to recommend it. The aim of the law should be less to punish crime than to prevent the manufacture of criminals. One of the most important recommendations of the recent valuable report of the rev. chaplain of Newgate enforces the careful classification of prisoners, in order to avoid dealing with the novice as with the expert. He urges that we should not continue to make habitual criminals by "indiscriminately" associating the old and hardened offenders with the new, and thus bring down men comparatively pure to the depraved notions of those whose lives have been one catalogue of crime." These are wise words; and a means of distinguishing between the offender who has been driven or seduced into his first violation of the law, and the wretch who, by ill-fate or choice, has adopted a life of crime, becomes imperative, in giving these words effect. The use of the most adequate means of identification is simple justice to a man charged with crime. That his identification will be attempted is quite certain, and that it should be dependent upon the memory of a policeman, whose very instinct urges him to secure conviction, is a positive hardship. At the last Middlesex Sessions, six police sergeants and four constables swore to a special previous conviction of a prisoner who was able to prove to the satisfaction of a jury that he was in the West Indies at the time

of the alleged conviction. The evidence of a photograph, if not proof positive, would at least have been of more value than the memory of these intelligent members of the force.

In its actual working, the system has been found most satisfactory. In one prison the average number of prisoners has been reduced from one hundred and sixty to one hundred; and this, according to the testimony of the governor of the gaol, is mainly due to the operation of the system of identification by photography. To the habitual and confirmed criminal alone, the preservation of such a pictured record can give cause of uneasiness. His career of crime may, by evidence of multiplied convictions, be cut short by one long imprisonment, instead of being permitted to consist in repeated outrages on society, and repeated brief punishments; the community suffering, in such case, the double evil of many outrages and much cost in the frequent repetition of trial and conviction. To the innocent such a record of identity can bring only safety; the system, like the law itself, being "for the punishment only of evil-doers, and for the praise of them that do well."

Correspondence.

IS THE PAPER A CAUSE OF FADING ?

DEAR SIR,—While so much is being said and written about the fading of silver prints, and everything connected with the production of silver prints has undergone the strictest investigation, the silver bath, the albumen, the toning bath, the hypo, the washing, the mounting, and mounting boards, enamelling &c., have each been the subjects of discussion upon which permanency has more or less been promised; but there is yet one subject which has received but little attention, that is the *paper*. I have for some time thought that the cause of fading lies as much, if not more, in the paper than in the silver; but, no doubt, the chemical combination with the paper does the mischief.

Now, if silver prints must fade, why not the negatives? Silver is the foundation of both, and hypo is generally the fixing agent of both, yet we do not hear of the fading of negatives. I have negatives and positives on glass of sixteen years' standing as permanent as when first produced, and during that period have produced some thousands of negatives, among which I have never yet detected a faded or even a cracked film. Sometimes the fading of prints has been ascribed to the albuminized paper, yet we are using a preliminary coating of albumen for our negatives. At present I do not see our negatives fade any the more for that.

Now, it seems to me, that the great want is a paper prepared impervious to moisture. *Is this an impossibility?* Cannot some of our scientific friends suggest the means of manufacturing such an article? For if it is possible to prepare such a paper, I cannot believe that there would exist a necessity for the fading of silver prepared prints, any more than there is for the fading of silver prepared negatives or positives on glass.

In conclusion, if what I have written is worthy of notice, use it; if not, destroy it, as I am not anxious to rush into print; still, I cannot help feeling that every photographer would be interested in such a prepared paper.—Yours truly,

JOSEPH STOKES

28, Grey Friars' Road, St. Peter's, Ipswich, Feb. 14, 1871.

CLEANING VARNISHED NEGATIVES.

DEAR SIR,—If you think the following worth a place in your valuable journal, it is at your service.

Having tried many methods of cleaning varnished glasses, I may venture to say that the one I now use is at once the cheapest, simplest, and most effective that could possibly be devised, and answers perfectly. It is as follows:—

Have ready on the hob a kettle of boiling water, into which throw a handful of common washing soda. Provide a large, flat, shallow porcelain tray, into which put as many of your glasses as will cover the bottom of it, varnished side uppermost; then pour your boiling soda water on to them, and imme-

diately commence rubbing the varnished surface with the end of a piece of stick made broad and flat on purpose, holding them down with another similar piece. By this means the varnish can be pushed off the glass with the greatest ease, and without sealding the fingers. The soda water should be returned to the kettle again, to be in readiness for the next batch of plates, as it is important that the water should be boiling when it is put on to them. The same soda water will do a very large number of plates. After removing the varnish, the plates should be passed through a dilute solution of hydrochloric acid to remove every trace of the soda, then well rinsed, and dried with a clean cloth; and may be coated with albumen or tunicare, and will be found to work as well, or even better, than new plates.

BENE-VELIS.

REDUCING OVER-PRINTED PROOFS.

DEAR SIR,—Having over-printed some photographs, I toned and fixed them; I then put them into a weak solution of cyanide of potassium. Much to my delight, they became gradually light, and did not change colour as they will do when left long in hypo soda. I should like to know if any of your readers have tried the like experiment.—I remain, dear sir, yours truly,

G. A. NICHOLSON.

1. *Green Street, Grosvenor Square, W.*

[If the cyanide solution be used very dilute, it will answer well. The danger is, that if in any degree too strong, the prints rapidly reduce too much, and in an irregular, granulated fashion.—Ed.]

CARBON V. SILVER.

SIR,—For the information of those who believe me capable of shirking Mr. Johnson's challenge, kindly make it known that I accept the same, subject to the following conditions:—

1. All prints to be printed from the same negatives.
2. The number of negatives to be not less than six; half to be selected by myself, the other half by Mr. Johnson.
3. "Dodges" to be allowed in the printing of the pictures.
4. Two referees to be chosen, one my selection, the other Mr. Johnson's. No one having any connection with carbon interests to be selected.
5. The decision of the referees to be published in the photographic journals. Should the referees be unable to decide, the matter to remain an open question for the decision of individual opinion at the next photographic exhibition held in London.

Although "X. Y. Z." has laid himself open, most temptingly, to correction, in deference to your expressed wishes, I forbear. I cannot, however, "strike my flag" without putting the query, What have I done to create such a whirlwind of indignation, such a sea of "hot water?" I will tell you what I *have* done, under difficulties from which most men would have shrunk. I have contributed to the pages of the News for a period of nine years; during that lengthened period, the results of my studies, experiments, and practical experiences have been freely given to aid photographic progress, whilst I have lost no opportunity of upholding the dignity of the art. I admit that I have sometimes hit hard at false theories and empirical suggestions. I have, nevertheless, stood up in defence of those who are sometimes mercilessly lashed without just causes, or an opportunity of defending themselves.

The question has sometimes been put, What can a mere printer know about pictures or art? I will explain. Some years since I was fortunate enough to have been taught the alphabet, and nature having kindly presented me with a pair of eyes, I have made good use of both. And I have the satisfaction of knowing that *my selections* always hold a first rank in the estimation of accredited art critics. Enough of this; I have to deal with the rise and progress of the recent contest.

In the performance of what I conceived to be my duty, I had occasion to describe certain tests which verified preconceived ideas respecting the causes of the fading of silver prints, and to show the necessity of adopting every available precaution to avoid such causes. I stated that the end of silver printing is *not yet*, strengthening the remark by some reference to the present state of carbon printing, which I described as having been "tried, and found wanting." This assertion was made on the authority of a lengthened investigation I made personally. I entertained no prejudice against Autotypy. I am not enamoured of silver printing; on the contrary, I regard the process as one of present expediency; by no means do I look on it as

one of permanent adoption. This view of the matter, however provides no rest-and-be-thankful kind of excuse for standing still. What would be thought of a farmer who, in view of a future lease which would give him permission to plough up his grass lands, gave his fields over to nature to produce the best crops she could without assistance, whilst the old covenant was running out?

Now, sir, having briefly stated the cause, I now proceed to review the effect. You, sir, criticised my remarks on carbon printing at some length, and in such a way that I felt in honour bound to respond, although I entered on the task with much reluctance. Had the discussion been confined to our two selves (yourself and me) it would have ended as it began, amicably; but the entrance of a troop of sharpshooters into the arena directly changed the character of the controversy. I was assailed with shafts of ridicule, my arguments were ironically distorted, private pressure was brought to bear against my deterioration to resist to the last word. My chief witness was shut out of court unheard; in short, every species of intoleration which my imagination had hitherto associated only with packed meetings and bucolic feudalism were brought to bear against my unlucky self. I am compelled to stop short to exclaim, most assuredly, sir, you have good reason to ejaculate, "Save me from my friends"! one among whom has done his best to prove the degeneration of photographic morality; another has led your readers into a supposition that you stand in need of prompters; a third and fourth have rushed in with utterances too terrible for "setting up." Surely, with these facts I can well afford to stop the contest. Most certainly I require no further argument to prove my case, for a system that cannot hold its own in sober discussion is, of a certainty, doomed to die out. A process which cannot bear even the pressure of inferences reasonably drawn is, at its best, a rotten affair indeed.

In conclusion. Can it be that I have over-estimated the wishes of photographers to continue learning and progressing? Is the art so hemmed in by selfishness and egotism that free discussion must be regarded as an institution crumbling to ruins? If such be realities, the sooner all earnest working men quit the field the better. The last, however, among the retiring ones will be,—Yours truly,

W. T. BOVEY.

PS.—I have "hauled down the flag" of defiance.

[Although we expressed a wish in our last that the controversy should end at that point, each of the disputants having been heard fairly and fully, as an indulgence to an old contributor, we allow him the last word; and our readers will form their own opinions as to how far carbon holds its own in the discussion. In justice to Mr. Bovey, we ought to explain his allusion to his "principal witness" having been "shut out unheard." In one of his letters he quoted the recently expressed opinion of the French correspondent of a contemporary photographic journal, who was advocating the use of glass or enamel plates for carbon printing as superior to paper. As, although the remarks quoted were unfavourable to carbon prints on paper, the gentleman in question has at times been one of the most enthusiastic advocates of carbon, and in the letter in question was advocating carbon prints on enamelled plates as likely, if introduced, to beat paper portraits out of the field, we did not feel it fair or in good taste to drag his name into the controversy by the quotation of isolated remarks which might subject him to adverse criticism in pages to which he was not in the habit of communicating. The opinions expressed of this gentleman formed the principal evidence referred to, and was thus shut out. Those interested sufficiently in the matter can read the opinions in question in our contemporary of February 3rd.—Ed.]

THE OWNERSHIP OF THE NEGATIVE.

SIR,—Concurring in the view expressed by your correspondent, Mr. J. Cunningham, as to there being no doubt whatever of a portrait negative (taken in the usual way) being the copyright of the photographer, and not of the sitter, permit me to adduce two somewhat analogous instances in support of his argument afforded by my own experience of other professions.

Previous to adopting photography, I practised as a land surveyor, and afterwards, for several years, was actively engaged on the English and colonial press in the capacity of reporter.

Surveyors always consider the notes in their field-book to be their own property, furnishing, in the usual course, a plan of

the property to their employer or client, and (in my own recollection) an assistant employed by a surveyor in California was, by a law court of that state, confirmed in his right to refuse to deliver up his field-book of an uncompleted survey, being obliged, however, to furnish a plan upon seals of the portion he had executed for salary received.

Reporters likewise consider their note-books to be their own property, and all that the employer can legally demand is a fair transcript of memoranda therein contained.

In the above instances, the surveyor's field-book, and the reporter's note-book, may fairly be considered as negatives from which it is the author's sole and exclusive right to produce the ultimate results, towards which they serve as the indispensable means.

Availing myself of this opportunity, I would ask again whether any means exist for protecting from imitation an original design for engraving mounts for cartes-de-visite and other photographs? Having conceived an idea which I confidently believe would, by general adoption, give a considerable impetus to the demand for portraits, I am anxious to make it known, and only hesitate because I am told at Stationers' Hall that registration will protect simply the particular engraving from imitation, without affording any security against the principle being copied, with slight variation, by any one desirous of evading the moderate royalty which I propose asking.

In conclusion, will you excuse my suggesting that the gentleman whose condescension you editorially give such prominence to in your last number would be wise in relieving his customers from the publicity of the fact of his graciously "feeling inclined to yield" to their wishes?—the fact that he asks £25 as an equivalent in a great measure reducing the weight of obligation under which he places them.—I am, yours obediently,

A COLONIST.

Clifton, February 20th, 1871.

COPYRIGHT IN PHOTOGRAPHS.

SIR,—I am sorry that "An Old Photographer" proposes to postpone pointing out some of my errors until I have "quite done." If I do not try your patience, the time is still distant when I can write *finis*, for the subject upon which I am writing is by no means exhausted. I am also sorry he thinks the correspondence has been spun out to a wearying extent. If such be the case, I alone am to blame, as my opponents have long since withdrawn from the contest. I can only say that endeavour has been made to write as tersely as the subject permitted, and I feel sure that you will readily concede opportunity for "An Old Photographer" to correct my "manifest errors." To him, perhaps, the law of art copyright is a matter of indifference, but to many of your subscribers I know it is otherwise by communications which reach me respecting it.

In a recent review of the latest work on copyright, there occurs this passage, which is worth repeating:—"There are very few men indeed who are not to some extent interested in the law of copyright; while there are scarcely any who know much about it. Yet, as it forms the only protection that artists, authors, sculptors, engravers, photographers, designers, and numerous other persons, can rely upon, it is not too much to say that they ought to study it and to learn it thoroughly, in order that they may not only define their own rights, but avoid danger and trouble by respecting those of other persons."

Apropos to my letter on "Ownership of Negatives" in your last number, a case was settled on the 18th instant which illustrates the ignorance existing amongst photographers with reference to their rights:—

Mr. J. J. Elliott, of the firm of Messrs. Elliott and Fry, Baker Street, summoned Teresa Conroy to appear on the 3rd instant, at Wandsworth Police Court, to meet his complaint of selling two copies of a photograph of Mr. John Bright, M.P., the copyright of which was vested in complainant. At the hearing, complainant was represented by Mr. George Lewis, junr., well known in connection with copyright prosecutions; the defendant was without legal assistance. As I am informed, when it became necessary to produce the original negative of Mr. Bright, or an impression therefrom, for comparison with the alleged piracies, they were not forthcoming, complainant having forgotten to bring them. The magistrate then adjourned further hearing until the 11th instant, for their production. The matter was brought under my notice, and, at the request of defendant, Mr. J. J. Merriman (of the firm of Merriman, Powell, and Co.) appeared on her behalf. I

wrote to Mr. Bright, requesting to be informed whether the prosecution were sanctioned by him. To that letter I received the following reply:—

"Rochdale, February 8th, 1871.

"SIR,—My father desires me to write and tell you that he is sorry he cannot write to you himself, as at present he is obliged, on account of his health, to abstain from letter-writing as much as possible. He is exceedingly sorry to hear the story you relate in your letter. He has had nothing whatever to do with it; and if his consent had been necessary to proceed with the prosecution, he certainly should never have given it, as he condemns the whole proceedings. He hopes, however, that some means will be found to help the poor woman out of her difficulty.—I am, yours truly,

(Signed) MARY H. BRIGHT.

At the hearing on February 11th it was contended by Mr. Merriman that the copyright (if any) was vested in Mr. Bright, the negative having been produced by his permission, and that there was no evidence to prove he had assigned his right to the complainant. The negative was produced, and also the certificate of registration, which described the photograph as being a vignette, three-quarter face. Here was a discrepancy, for the negative was not a vignette; it also stated that a photograph was annexed. The magistrate held that he was entitled to have the best evidence that could be produced, and adjourned the further hearing until the 18th instant, for the production, from Stationers' Hall, of the memorandum of registration with photograph annexed.

On the 18th instant defendant, with Mr. Merriman, appeared, when they were informed that a letter had been received from Mr. Lewis, abandoning the prosecution. To this Mr. Merriman demurred, and claimed the decision of the court. The magistrate thereupon dismissed the summonses, and adjudged the complainant to pay forty shillings costs to defendant.

Now, all this annoyance and expense to both parties would have been avoided if Messrs. Elliott and Fry had studied the first section of the Copyright Act, and had taken care that their transactions had been conducted in accordance therewith.

When distinguished persons give sittings to photographers, for the purpose of publication, they do so, I presume, to afford the public the opportunity of obtaining their portraits. They have no wish to retain the copyrights themselves, and still less desire to create an exclusive monopoly for the benefit of the photographer. Her Most Gracious Majesty, I think, would be sorry to hear that any of her subjects had been fined or imprisoned for making copies of her portrait. I can understand when a modern "Aspasia," whose "charming copyright photograph" delights "Justitia," visits Baker Street for the purpose of having her portrait taken, she may do so with a double view of benefitting herself by its sale, and, at the same time, advertising her charms by a means denied in olden time to her predecessors Phryne and Lais.

That a knowledge of the law of copyright should be acquired by producers and sellers of photographs is a proposition which cannot be denied. Recently a firm in the city applied to me for advice with reference to certain legal proceedings they were threatened with for infringement of the copyright of a photograph relating to a certain royal personage. Upon enquiry, I found that copyright had never been acquired, and, further, that the photograph in question being libellous, there was no property existing in it at common law.—I am, sir, your obedient servant,

London, February 20th, 1871.

J. CUNNINGTON.

COPYRIGHT.

SIR,—I am too old a hand to complain of criticism on anything I may happen to have written; that is the penalty writers must submit to. I do not complain that Mr. Cunnington differs from me in his views of copyright and piracy; he has a perfect right to do so; and, on personal grounds, I should not claim space in your Journal to notice them; but, seeing that large commercial and pecuniary interests are at stake, I think I should be wanting in my duty to my brother photographers if I did not raise my voice, warning them not to rush hastily into a course of action on the faith of Mr. Cunnington's law, but first to seek the opinion of some qualified legal adviser. I earnestly entreat them to pause, or they may find, too late, that they are landed in an awkward position.

It must be remembered that Mr. Cunnington is not a professional lawyer; and, without claiming any infallibility for my own knowledge, I venture to think that many of your correspondent's notions of copyright law, and methods of interpreting

a statute, would simply provoke a smile if urged before any tribunal of lawyers, and it is by such a tribunal any case must be determined.

I have no intention of entering into a controversy with Mr. Cunington. I have neither the inclination nor the time for it, nor would any good result.—I am, sir, your obedient servant,
P. LE NEVE FOSTER.

DISSOLVING VIEWS WITH ONE LANTERN.

DEAR SIR,—Allow me to ask "Silvester" how otherwise such an attack as his could be answered except as joke for joke, or, in his own words, sheer nonsense in reply to sheer nonsense? There is scriptural precept for this mode of proceeding. I leave his persistence in uncharitableness to the estimation of your readers, as also his attempt to pervert the jocular idea of the cucumbers into a serious recommendation of the experiment, instead of, as was intended, a laughable hit at those who would attempt either impossible or unprofitable ones. I also wish to inform "Silvester" that the idea is not mine; had he been better read in standard literature, he would have known it. His remarks respecting the passage of the light from one system of lenses to the other are, in the main, correct, but, as he has done more than once, he has over-shot his mark: perfect darkness will not continue until the light has reached the centre of the other optical system, but only relatively so as to its distance from such centre.—Yours respectfully,
J. MARTIN.

106, High Street, Ilfracombe.

PERSONAL INSTRUCTION FOR PHOTOGRAPHERS.

DEAR SIR,—My apology for troubling you is, that I think I can call attention to a universal want that I have not seen expressed, but which, I believe, widely exists amongst professional photographers everywhere. I mean the difficulty or impossibility of obtaining skilful personal tuition.

I am an example. I have, I believe, as good a studio, apparatus, and fittings, as any in Brighton, and that is saying no little; but, unfortunately, I am a dunce. I can work away in one direction well enough, but have neither time (for the mill must be kept going) nor ability to find out how to make the most of the means at my disposal, at the same time am very anxious to get good results, so as not only to compete with my neighbours, but also to keep pace with the times. Not only that, but in any walk a man may undertake I hold it his duty and interest to cultivate himself by all the means in his power.

Now, sir, it would be a good thing if some gentleman of established reputation and undoubted skill would make it his business to call round on all those who desire it, and, for a certain and liberal fee, just set them straight and tell them where they are wrong. I believe he would be received with open arms and hearty welcome, and the improvement to portraiture at large would be very desirable, not only to the profession, but would be appreciated by the public. Do you know anyone who would come to me for a week?—I am, sir, yours respectfully,
H. S.

Brighton, February 16th, 1871.

[It is very probable that such instruction can be obtained for a proper consideration. But gentlemen of established reputation could scarcely be expected to call round in the manner suggested. Photographers requiring such instruction must be prepared to pay a high rate for it, as there are but few photographers of ability and reputation who have not specific business, which would be neglected whilst they were giving lessons.—ED.]

ARITHMETICAL CURIOSITY.

SIR,—There is really nothing remarkable in what your correspondent points out, in last week's News, as an "Arithmetical Curiosity." The hand of the clock going over the face once points in succession to numbers which, when added together, amount to the constant sum of 78. Now, as the number of years of our Lord are indefinite, and may run to any number whatever without limit; and as, at every interval of 78 years, there will be a number divisible by 78, it is clear that when 24 of such intervals have elapsed, the year will be 1872. Why your correspondent assumes the hand to pass over the face only once in the 24 hours I do not know, except that it is convenient to produce the number 1872, which he desires. Let him take what is the fact—viz., that the hand goes twice over the face in 24 hours—and then he will have twice 78, or 156, as his factor, and the year will then be 3774, and not 1872.

The fact is, that any assumption may be made as a basis; and, as the number of years is indefinite to choose from, there is no difficulty in finding one which will be any multiple of the assumed basis that may be fixed upon.

By-the-bye, your correspondent speaks of a "sidereal" day. This is, no doubt, a slip. He means evidently a "solar" day as the former is, as we all know, a little short of 24 hours.—I am, sir, your obedient servant,
ARITHMOS.

THE COMPLETION OF TIME.

SIR,—A correspondent has noted in your paper that the hours of the clock added together and multiplied by the twenty-four hours of the day gives the number 1872.

I do not know whether his idea is that next year, 1872, will be, as it were, "the completion of time," and that the saying of the angel in the Revelation will be then fulfilled, that "time shall be no more." But it is somewhat remarkable that if he takes the Jewish mode of calculating time, and, in like manner, adds the figures together, and, in addition, includes the various elements or representatives of time, he will obtain the figure 4,004, or the exact age of the existence of the world under the old dispensation. Thus the hours from sunrise to sunset would give 63 which, being doubled, equal 126 and multiplied by 24 " " 3,024 to which add the different components of time, i. e. :—

One year	365 days
Months in year	12
Days in month	31
Days in fortnight	14
Days in week	7
Minutes in hour	60
One day more for leap year	1

Gives 490
which being doubled, equal 980

4,004
WILLIAM JUPE.

Your obedient servant,
336, Kingsland Road, February 21st.

PHOTOGRAPHIC MEDAL AT ART WORKMAN'S EXHIBITION.

DEAR SIR,—Permit me to correct an error in your issue of last week which your correspondent has made relative to an Art Workman's Exhibition held in Manchester. The one which he evidently means, and to which I contributed, was held at the Agricultural Hall, Islington, London, and the silver medal was awarded to me for a series of untouched photo studies and carte-de-visite portraits, and not for a single photograph.—I am, yours truly,
AUGUSTUS LAFOSSÉ.

Rock Mount, Higher Broughton, Manchester, Feb. 20th, 1871.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.
Report of the Council.

THE proceedings of the past year, although destitute of any important original discovery, may, nevertheless, be regarded as affording indications of progress in many branches of photography, and may be said to furnish evidence of a wide-spread diffusion of art-knowledge, which has been productive of improved results both in portraiture and landscape, and did not fail to exert a marked influence on the quality of the works contributed to the Society's last annual exhibition.

The year's proceedings commenced with the paper read by Mr. Samuel Highley at the last Anniversary Meeting, and entitled "The Magic Lantern in Relation to Photography," which was illustrated by an extensive array of apparatus. At the March meeting, Mr. W. J. Stillman brought forward a new "Theory of Photographic Development," according to which the sensitive film is supposed to be in a normal state of continual vibration, and to receive its impression by virtue of the actinic wave impinging upon it, producing a sort of inertia which immediately effects the disunion of the elements composing the body thus submitted to the action of the chemical rays. The author, in the course of his remarks, hinted at the possibility of the transference of the undeveloped impression on a dry film to another film placed in con-

tact with it without the agency of light; and also stated his conviction of the futility of all attempts to produce photographs in natural colours, an opinion which Mr. R. W. Thomas afterwards took occasion to examine from an independent point of view, and arrived at the same conclusions.

Another paper, read on the same evening, was descriptive of Mr. R. H. Courtenay's Photo-Printing and Heliographic processes, some features of which appeared to be similar in principle to Herr Pretsch's method of working, or that formerly known by the name of the Photo-galvanographic Process. A suggestion to this effect brought on a lively discussion, which was revived at the meetings of May and June, when a large series of Paul Pretsch's works were exhibited. The prize pictures of the Amateur Photographic Association were placed on view at the March meeting.

In April Dr. Mann gave a description of Mr. Browning's Stereograms of the Planet Mars, and showed four sets of pictures centered on different parts of the body of the planet. At the same meeting, Dr. Anthony gave an interesting paper entitled "The Photographic Atelier in 1870." In this communication a novel arrangement of studio and operating-rooms was proposed, which economized to the utmost the space available for the working of the camera. The suggestion was, in some particulars, approved; but a disadvantage presented itself in the circumstance that such a form of studio would only permit of photographic operations being conducted under one invariable system of lighting, and the production of pairs of portraits might be attended with difficulty.

The May meeting was occupied with a description of Mr. Burgess's mode of producing his Carbon-eburneum Prints, specimens of which were exhibited. Mr. J. W. Swan had a paper on "The Chemistry of the Carbon Process," which has been reproduced in many of the foreign journals; and Mr. England favoured the Society with some "Remarks on the Dry-plate Processes," and showed comparative results of his working a modified gum-gallic process against collodio-albumen, coffee, and highly sensitive plates prepared with acetate of morphia. When employing the gum-gallic process, Mr. England uses a more dilute preservative, which, it is said, gives increased sensitiveness with less chance of blurring; whilst for developer he much prefers the use of alkaline pyro, instead of the gelatine-iron solution originally recommended. Mr. Gordon, however, preferred the original formulæ, which gave the keeping qualities, the lack of which Mr. England had experienced. This branch of practical photography received further elucidation at the November exhibition, where Mr. Gordon showed prints from negatives taken by five different dry processes against the ordinary wet plate. The gum-gallic method was followed in the production of the pictures shown by Mr. Grant and Mr. Whiting, and favourable specimens of collodio-albumen work were seen in the pictures of Messrs. Giberne and W. D. Sanderson, coffee, and tannin with malt, being likewise represented.

Photo-mechanical printing formed the subject at the June meeting, Mr. C. F. Jessen giving an account of the Lichtdruck process, as practised by Messrs. Ohm and Grossmann, of Berlin. Specimen prints were shown, including a variety of subjects, and the largest plate measured 15 by 12 inches. The results of a somewhat similar process called Heliotype, and worked by Messrs. Edwards and Kidd, were shown at the exhibition, where, besides, there was a magnificent display of Woodburytypes of the old order, and a single specimen of a new photo-cu-graving process, which Mr. Woodbury has kindly promised to bring before the Society when perfected.

Carbon printing has progressed during the year, as evidenced by the results shown by Messrs. Sarony and Co., Spencer, Downey, Window, and by the government departments. A noteworthy circumstance in this connexion is the fact that the Scarborough firm first named have succeeded in producing for Messrs. Agnew a reproduction (in carbon) which extends to the extraordinary dimensions of 45 by 21 inches.

Photo-crayons of fine quality were shown at the exhibition by Mr. R. H. Preston, of Penzance, and by Messrs. Vandye and Brown, of Liverpool; but it does not appear that much progress has been made in their direction during the past year. The same remark is applicable to the art of photo-enamelling, which was represented last November by one foreign and three English exhibitors. Enlargements have improved in quality, several good examples being shown in the exhibition, and a couple of subjects of exceptionally high merit were forwarded as the work of an American confrere, Mr. Albert Moore, of Philadelphia. A special application of photography to the delineation of insects, diatoms, and other microscopic objects on an enlarged scale, has been very successfully carried out during the year by Mr. Thomas Higgin, president of the Liverpool Amateur Society, with the assistance

of Messrs. Robinson and Thompson. A series of these micro-photographs constituted an important feature of the exhibition, and were greatly admired. The progress of art photography was admirably illustrated at the exhibition in the sea-views and landscapes of Messrs. Robinson and Cherrill, the combination prints of Mr. F. C. Earl and Mr. Hubbard, the portrait studies and cloud effects of Colonel Stuart Wortley, the portraits of Valentine Blanchard, R. Sliugsby, Rejlander, Brookes, Wane, and a host of others.

At the December meeting two papers were read. In one of them Mr. H. B. Pritchard described his mode of employing the collodio-chloride process for the reproduction of faded prints, accompanying his remarks by the display of a series of highly-illustrative specimens. Mr. Daniel Spill gave an account of a material to which he applies the name of Xylonite, as being manufactured from gun-cotton or xyloidine and certain oils or hydro-carbon solvents. From the variety of articles exhibited, the wide applicability of this subject could be inferred, and Mr. Spill showed two kinds of adiacinic material suitable to photographic tents and windows. It will be in the recollection of the members that the last meeting (January) was entirely occupied with the full description of Mr. Henry Cooper's mode of working the collodio-bromide process, which, in his hands, seems to have given very satisfactory results, and may possibly be further improved by the addition of chlorides, as suggested by the author.

Photography has of late been brought into requisition, and made to play an important part in the operations of war on the continent; thus the Topographical Depot at Berlin has regularly furnished route-maps on a reduced scale for the guidance of the German commanders in foreign territory; and besieged Paris itself has for several months partly depended for its communication with the provinces on a system of pigeon post, in which despatches and intelligence were carried in the form of minute photographs, afterwards requiring the aid of a microscope to be deciphered. At home the help of photography has been invoked in connexion with criminal law, and for the identification of offenders. It has likewise fulfilled important functions in recording the phenomena of the recent solar eclipse, Lord Lindsay and Mr. Young at Cadiz, and Mr. Brothers at Syracuse, having, it is reported, been successful in securing good photographs of the corona.

The resolution passed at the last anniversary meeting restricting the issue of the Journal to eight months in the year, and limiting its scope strictly to the purposes of an official record, has had the effect of very considerably reducing the expenditure upon the Journal without interrupting in any way the direct communication of the Society with its members. A new contract was entered into with the publishers, and the cost of editing reduced, so that this item in the balance sheet now shows a reduction of about one-half upon the corresponding outlays of previous years. The financial success of the exhibition is also a matter of congratulation; for although the Society might be inclined to consent to a moderate pecuniary loss in consideration of the benefits conferred, it is encouraging to find that the public are willing to pay (on one day in the week at least) for admission to view the best collection of photographs of the year, and that the amount so realized, supplemented by the profits on the sale of catalogues, was nearly sufficient to cover all the charges incurred in connection with the exhibition. The galleries remained open for upwards of three weeks, and were well attended throughout this period, great interest being manifested in the works of art therein displayed.

Thirty-five new members have been elected during the year, which, allowing for losses by death and retirement, raises the number of last year (240) to as many as 263 present members. Amongst those who resign their connection with the Society, the council regret the loss of two well-known names, Mr. J. Durham and Mr. B. B. Turner, who have interested themselves in the proceedings of the Society since its first formation. The council have greater cause of regret in the circumstance that we have lost by death three distinguished members of the Society. They are the ex-president, Sir Frederick Pollock; the senior vice-president, Rev. J. B. Reade, F.R.S.; and Mr. Thomas Ross, Optician. To this report are appended obituary notices of the deceased members.

(To be continued.)

Talk in the Studio.

THE WOODBURYTYPE PROCESS IN PARIS.—We are happy to learn that the establishment at Asnières, built by MM. Goupil and Co. to carry out the photo-relief printing process, reported to have been destroyed, is found to be uninjured, and

will, in a few days, be again in full work. Mr. Smith, the superintendent and manager, has been engaged in the defence of Paris, having in charge the electric light, the apparatus used at Asnières for producing light for photographic printing having been requisitioned for purposes in connection with the defence. Although in a post of danger, as many as 400 shells in one day falling within 200 yards of the position of the electric lamp, Mr. Smith was not injured, and only lost eighteen pounds in weight through short rations.

LICHTDRUCK.—The photo-collographic processes, which have received on the continent the generic name of Lichtdruck, continue to progress. We have just been favoured by Dr. Liesegang with some admirable photo-micrographs printed by Pastor Thalén, who has worked out one of these processes.

INDIAN CEMENT.—The basis of this cement always consists of "gluten," made from wheat flour, by washing a quantity of the best wheat flour in a running stream; as long as any "farina" remains the water will run off white from the muslin cloth in which the flour is contained. When the water runs colourless, take out the coagulated mass and beat it into a viscid dough, in a clean Wedgwood mortar, or between two clean pieces of hard wood; it will soon become like birdlime. For most purposes this gluten, called "nusliestoh," or "sitting down," is mixed with about a quarter of its weight of coarse sugar or treacle, and the same quantum of newly-burnt quicklime in fine powder. Coarse furniture, fine cabinet work, chinaware, glass or metal, or wooden mountings, horn and ivory to each other and to wood, stone to metal, have all been repeatedly joined by—E. O. S.—*English Mechanic*.

COPYRIGHT CASE.—A few days ago, at Wandsworth Police Court, Mrs. Conroy, of Battersea, appeared for the third time to answer a summons for selling copies of a photograph, or the negative of a photograph, of Mr. John Bright, M.P. The complainant was Mr. Elliott, a photographer, who claimed to be the owner of the photograph, and he alleged that the copies were sold without his consent. On the case being mentioned, Mr. Merriman, who defended, was informed that the summonses had been withdrawn. Mr. Merriman expressed surprise, and said he had not received any intimation of that. He had appeared at some personal inconvenience, and therefore he asked for costs. Mr. Dayman then made an order upon the complainant to pay 40s. cost to the defendant.

"ANTI-PHOTOGRAPH DEMONSTRATION."—*Punch* says:—"A meeting of the Government Intimidation Society was held last night at the Donkey's Head, to concert measures for expressing the indignation of the People at the tyranny practised on convicts in prisons at Liverpool and elsewhere, in compelling them to sit for their photographs. The chair was occupied by Mr. Slackjaw, who announced himself as a representative of the Working Man. He was not a thief, but advocated equalization of property, and sympathised with his fellows. Prison authorities had no right to photograph a man who had not been sentenced to undergo that process, which was a gross indignity. The People must assemble in their thousands, and tell their tyrannical Rulers that they would not stand it. Mr. Ruffles, an habitual criminal, said that he had his self been photographed in gaol. But he had done the beggars. He had shammed conversion, pretendin' to be a penitent thief, and pulled a mug accordingly whilst he was took. He didn't much fear he'd be knowed if he was lagged again. He was a man of few words, and so, to conclude, would move a resolution that this here meetin' take immedate steps to 'old a demonstration in Trafalgar Square, with a view to overawe the 'Ome Office, and demand perfection of coves in quod from bein' photographed agin their will. The resolution, having been seconded by another thief, was then put from the Chair, and carried by acclamation. Although the photographic grievances may seem exclusively a thieves' question, the demonstration against it, about to come off in Trafalgar Square, is not expected to differ, as to those who will take part therein, from other customary displays of menace in respectability."

To Correspondents.

F. ASHTEAD.—Honey plates should be washed with distilled water before development, and then developed with pyrogallie acid with a very small trace of citric acid and nitrate of silver added. To gain intensity, more silver and acid may be added after the image is out. 2. The use of a preliminary coating of india-rubber on the plates will not injure the nitrate bath.

HERPESUS.—Much depends on circumstances and individual skill in working different processes. As a rule, we should prefer the collodion transfer process for enlargements, as involving the least variation from ordinary operations, as the least trouble, and, being the most sensitive process, best suited for the uncertain light in our climate. The next process, nearly equally simple, is the production of an enlarged negative from a transparency, and printing in the ordinary way. The solar camera is excellent when well managed, but, except where it is in constant use, it is troublesome for use in the hands of ordinary portraitists. Development printing with the use of Mr. Solomon's magnesium lamp is simple and convenient to those familiar with development printing operations. 2. There are two or three causes for your failure in producing satisfactory collodion prints, the chief of which is probably short exposure and over-development—the latter especially. Plenty of exposure, plenty of acid in the developer, and rigid protection of the plate from light, must give you a clear image unless the chemicals are out of order. Toning with gold removes the rusty opaque effect of the shadows which is sometimes present, and it also aids in removing traces of foggy deposit from the lights, especially if, after toning, the plate be placed for a few moments in the hypo fixing bath.

G. T.—Although the offensive smell of the sample of paper you enclose would suggest doubts of its fitness for use, yet, as a matter of experience, we should have no hesitation in using it. Some of the finest prints we have seen, and which we have found to be most permanent, were produced on paper which had a villainous smell, as, indeed, the paper of the same maker generally had.

WAITING FOR FRIDAY.—You will find full details of M. Adam-Salomon's new system of lighting in our last volume, and also in our YEAR-BOOK recently published. 2. It is very difficult to remove stains from absorbent substances like wood. Iron stains on oak will produce something like the stains of writing ink. Oxalic acid will best remove them. 3. Your question, "What is the best way to make a good negative bath?" is somewhat too vague and comprehensive for a complete answer in this column; but we may state, in general terms, dissolve thirty-five grains of pure nitrate of silver in each ounce of pure distilled water, and to each pint add two grains of iodide of potassium. If everything be pure, such a bath will work well at once. If it fail, add a few grains of carbonate of soda. Sun the solution for a few hours, filter, and then try the bath, which should work well. 4. Fibrine of blood is a tough gelatine substance, obtained by washing coagulated blood, to remove all that is soluble, in cold water. The residue is fibrine. 5. Such a piece of wood, if free from warping, and of suitable surface, will answer. 6. Paint it grey.

ARTHUR THOMPSON.—Shellac varnish is made by dissolving shellac for troughs in wood naphtha or methylated spirit, at the rate of a drachm or more to each ounce. 2. Either glass or porcelain will serve if properly annealed. There are porcelain dishes expressly suited to this kind of work. Neither will injure the bath.

A. H. L.—We are uncertain. Try Mr. How, of Foster Lane.

G. LEAFANG.—The imperfections in your transferred print spring from various causes. The negative does not appear to be a suitable one for work of this kind; it is too hard and dense. The exposure has also been somewhat short, and the development somewhat long. The rusty portions of the deep shadows are due to the toning operation not having been carried on long enough to penetrate through the densest part of the deposit. The spots where the film has been torn are due, probably, to the use of a plate not quite perfectly cleaned. 2. For small pictures the enamel transfer paper, kept by most dealers, is best. For large pictures, coat plain paper with gelatine, as you have done—not albuminized paper, nor the back of albuminized paper. 3. Yes; we believe so. 4. We have often published instructions for transferring, but perhaps you will find hints on that point of most value to you in an article on page 373 of our volume for 1869.

E. ALLEN.—We regret that we have no facilities for writing intimations of the kind to which you refer. 2. We do not know of any special builder of photographic studios. The want exists, but has not been met.

M. MARQUAND.—Thanks. In our next.

J. J. BLACKMAN.—Except for special purposes, and to meet special necessities, a simple 15-grain solution of iron with 15 minims of acetic acid answers as well as any developer we know. Or add 15 grains of sugar-candy, and use half the proportion of acid.

W. W.—Both gloves and finger-stalls are pure india-rubber.

ISAAC WILDE.—Thanks. In our next.

N. N.—The *Photographisches Correspondenz* is published in Vienna.

R. L.—On page 83 of our YEAR-BOOK for 1866 you will find the article describing the use of Schlippe's salt for producing scarlet negatives. The same method is, of course, applicable to the toning of transparencies.

Several Articles in type, and several letters, are, from the pressure on our space, unavoidably compelled to stand over until our next. Several Correspondents in our next.

THE PHOTOGRAPHIC SOCIETY OF LONDON— ITS NEW PROSPECTS.

THE treasurer's report at the last meeting of the Photographic Society of London was one upon which all interested, not merely in the Society, but in the progress of photography, can, with propriety, be congratulated. We need not pause here to enlarge upon the importance to the progress of the art which is involved in the existence of a healthy active representative society. It is not alone to its ordinary meetings, and the papers and discussions, we should look for the action of such a society, but to its vast collateral influence. Its exhibitions alone are of incalculable service to the art and to its votaries. Its journal has been in times past—when the art was insufficiently advanced to afford scope for private enterprise in journalism—of enormous service to the art; and in a variety of other modes photography and photographers have been served by the Society. It might have been of more service, and it may still be. Some of the most expensive of its past efforts in early days were well-meant, but ill-judged; and for some years past its crippled financial position has limited its power to serve its members and the art. That crippled position is at an end. The Society is not only practically out of debt, but possesses the prospect of an income sufficiently in excess of its routine expenses to permit the anticipation of various projects of a pleasant character.

As photographers know, for a number of years the expenses of its Journal were swamping the Society, and even after the council had resolved to cease its issue as a journal of general photographic literature, simply issuing a monthly record of the transactions of the Society during the session, and so get rid of a large source of current expense, the old debt still hung like a mill-stone round the neck of the council, not simply hampering their action, but actually forbidding the contemplation of any steps involving the outlay of money. By the gradual operation of the system of strict economy to which the council bound themselves, the debt was materially reduced, and although a residue of the old debt of the Journal, of nearly £200, was due when the last balance-sheet was made out, we believe that at this moment the Society is practically out of debt. Its balance-sheet showed it to be more than solvent, but a portion of the assets were still in supposition. Since that balance-sheet was prepared, a number of gentlemen on the council have shown their confidence in the stability of the Society, and their immediate desire to see it free from the incubus of debt, by compounding for life membership, on the original terms imposed in the youthful days of the Society, namely,

the payment of a sum of ten guineas, several intimating their readiness to resume the payment of the annual guinea at any time when the position of the Society might render it desirable.

Thus out of debt, and with the prospect of funds accruing from the regular income of the Society considerably in excess of its routine expenses, members will naturally look forward to special boons to be received. In the admirably clear resumé of the position of the Society given by the treasurer at the last meeting, he stated that the income of the Society from subscriptions was £208 per annum; the income from the Journal, in round numbers, £50 per annum; and the income from the November exhibition, £28; making a total income of £358. Against this the expenses are, for rent and general purposes of the Society, £55 per annum; for printing the Journal, £60 per annum; salary of editor of the Journal, £50; expenses of the exhibition, £38; making a total of £203, and leaving a balance of £155 per annum to be expended for the advancement of the art and the benefit of the members.

This position and this prospect are to us sources of unmitigated satisfaction. We have always felt and expressed complete confidence in the Society, in the value of its influence, and in its power of recuperation from the crippled position into which a variety of untoward circumstances and some early mismanagement had plunged it. But after exultation, members will naturally ask: What next? To what purposes will the surplus income be applied? To this, at present, no definite answer can be given; but all concerned may easily feel assured that a council to whose energy and prudence they owe such a satisfactory position will not misuse the surplus they have been endeavouring to create. We may, however, offer two or three suggestions as to the probable and desirable action of a society with finances at its disposal.

One of the most valuable aids to progress is the maintenance of an annual exhibition; and as the Society has established and upheld one during the last few years of its financial struggle, it cannot be doubted that the exhibition will be maintained in future. Possibly some increased efficiency might be given if in future the exhibition could be kept open longer, and advertised more extensively. With funds in hand this might be done without risk, and it is by no means improbable that the increased income from the exhibition might fully cover the additional expense. As also connected with the exhibition, it is possible that the establishment of a series of annual prizes might be found of value in stimulating excellence, and giving the increased interest to the exhibition which generally attends competition. The wisdom of offering such prizes has, we know, been doubted. We do not enter into the discussion here, but simply remark

that we believe that the majority of those likely to compete, and within the ranks of those likely to take prizes, are in favour of such prizes. The Society has already dies for medals, and and the annual cost of the bronze or silver, and labour in striking the medals, cannot be great. Another use for medals would consist in carrying out an old resolution of the Society, namely, that the communication of papers to the Society of unusual excellence, and the announcement through the Society of discoveries and inventions, should be rewarded by a medal to be called by the President's Medal. This admirable resolution has remained in abeyance simply for want of funds; its revival and carrying out would clearly tend to the advancement of the art, by encouraging the communication of valuable matter to the Society.

But, perhaps, the most generally useful, and certainly most popular, method of applying some portion of the available funds of the Society will consist in the periodical distribution of presentation prints. To such a distribution members have an undoubted claim, not only because it is a natural and legitimate step, but because the present energetic president has, with a perfect apprehension of its desirability, repeatedly placed hopes before the members of future boons of this kind when the finances would permit the Society to venture upon such a step. Some such prints have already been distributed to members, but these have been chiefly due to the generosity of individual members. In future, more definitely organized steps can be taken in the matter; and here we may throw out a hint for the consideration of those concerned. It appears to us that presentation prints from a representative society should have a higher value than that derived from their excellence as pretty photographs. The prints themselves should have a representative character. Why should not the members receive through the agency of the Society an example of every novelty of any special value or importance which is introduced into the art? Country members of the Society at present receive but little in return for their annual subscription, save the satisfaction of assisting to maintain a representative society for the art they love. By the organization of such a system of presentation prints as that which we suggest, they would acquire a valuable *quid pro quo*, which would in all probability be so highly esteemed, that the Society might easily double or treble its number of members. We should suggest that examples, in succession, of the various carbon processes, of the various photo-mechanical processes, of the various new chemical printing processes, which come before the public from time to time, be selected as presentation prints. These might always be good or interesting as pictures, besides illustrating a process. They might also illustrate styles, or sizes, or special pictorial effects. Such a scheme, although comprehensive, need not be costly. In many instances the inventor or projector of a new method would willingly meet the Society on very moderate terms, the honour and publicity being an important element in the recompense. By the expenditure of a comparatively small proportion of the annual surplus, we are satisfied that a scheme of presentation prints might be established which would far more than compensate every member for the amount of his annual subscription, besides all the other advantages of the Society.

A variety of other useful purposes exist to which the Society might with propriety devote funds at its disposal. The establishment of a library of scientific and artistic works, for instance, might be found serviceable to some of its members, as also the establishment of a photographic museum, in which examples of everything illustrating the art and its appliances might be preserved. It is unnecessary, however, to consider remote contingencies. At present we have simply to congratulate members on their deliverance from the thralldom of debt, and the prospect of some very early and definite advantages arising from their emancipation.

OBITUARY.

WE have deep regret in announcing another gap in the ranks of eminent photographers. Mr. William White Rouch, of the Strand, died on the 18th inst., at Mentone, where, for several years passed, he has been in the habit of spending the winter, to avoid the severe cold of our own climate, so unsuited to the pulmonary affection from which Mr. Rouch suffered. Although only thirty-nine at his death, Mr. Rouch's name has been, as our readers know, for very many years associated with photography, first in connection with the firm of Burfield and Rouch, and subsequently as the senior partner of W. W. Rouch and Co., the firm having been for many years especially associated with the manufacture of Mr. Hardwich's collodion, under that gentleman's special sanction. It was not simply, however, as associated with the manufacture and preparation of photographic chemicals and apparatus that Mr. Rouch's name was connected with photography; he was himself a photographer of singular ability and taste, his landscapes being rarely exceeded for fine judgment in selection, choice of light, and unusual delicacy of treatment. Many photographers will remember his pictures exhibited in 1862 and subsequent years as possessing these qualities, and in the Conduit Street Exhibition of 1869 his views in the neighbourhood of Mentone were admirably illustrative of the fine taste and skill which characterized his work. His interest in landscape photography led to many improvements in photographic tents and out-door appliances devised as the result of personal experience.

Photographers will be glad to learn that the decease of Mr. W. W. Rouch will not cause any interruption in the business of the firm. His brother, Mr. S. W. Rouch, who for fifteen years has been associated with the business, and upon whom for years past, owing to the delicate health of his brother, the commercial management of the establishment has worthily devolved, will still continue in charge of the business, in the transactions of which no change will take place.

GUM COFFEE PROCESS.

OUR readers know that one of the dry processes producing the most sensitive plates is the gum coffee process of M. de Constant, a detailed account of whose operations we shall issue very shortly. We shall shortly have something to say on the very admirable examples with which M. de Constant has favoured us. In the meantime we append some details by Mr. Robert Day, of Bournemouth, who has been trying gum and coffee, and reports in the *Journal* of the Society.

No. 1.—Pure ground coffee 2 drachms
Boiling water 4 ounces.

When cold, filter the infusion into a bottle.

No. 2.—Gum arabic 1 drachm
Sugar candy 20 grains
Water... .. 4 ounces.

Dissolve and filter for use.

Mix together equal parts of Nos. 1 and 2 just before using. First of all clean the plates thoroughly, and then draw a camel's-hair pencil, moistened with diluted albumen (white of egg one part and water three or four parts) round the edges of the plates, letting the pencil form a margin on the plate of about three-sixteenths of an inch all round; when dry the plates are ready to receive the collodion. Sensitize until all greasy markings have disappeared, and wash well under a tap, finishing with a little distilled water; then apply the gum and coffee mixture, allowing it to flow over the plate and run off into the sink; pour some more over the plate, which may be returned to the stock-bottle; then set aside in a dark place to dry, when it will be ready for use.

To Develop the Plate.—First flood it with water for a few seconds, until the film is saturated; then pour on a two-

grain solution of pyrogallic acid; keep this on until the image is well brought out, then add a few drops of a solution made as follows:—

Citric acid	20 grains
Nitrate of silver	20 "
Water	1 ounce.

This will have the effect of making the image burst out in full vigour: keep pouring the solution on and off till the required degree of intensity is obtained.

The above constitutes the sum and substance of my first attempt in the way of dry-plate work; and having been quite an invalid ever since, I have been prevented from trying further experiments. I shall be glad to know that the method answers in other and more experienced hands, and hope that some dry-plate worker may be induced to give it a trial and report the results.

WASHED ALBUMINIZED PAPER.

THE employment of washed sensitive paper is a subject of very material importance to the photographic printer who has not yet embarked on the adventurous enterprise of carbon printing. Hitherto, all who have used this method of working seem to have succeeded so well in their efforts as to be mightily pleased with it in all its bearings, and have recommended its adoption, both on the score of simplicity and of moderate cost. In Germany many advocates have come forward, and in this country Colonel Stuart Wortley and several other photographers of eminence have been warm in its praise. This being the case, it is with some surprise that our readers will read M. Engelmann's experiences of the method, which are stated to have been obtained in actual practice on a large scale. M. Engelmann does not deny the superiority of printing in this way on several points, and believes, indeed, the method to be a useful one for amateurs, and in studios where but little work is executed; but the requirements to be attended to are, to his mind, too numerous and complicated for everyday working.

While, therefore, M. Engelmann thoroughly believes in the value of employing washed sensitive paper, and concurs in the opinion already frequently expressed of the great advantage afforded by the suppression of the daily operation of sensitizing, he nevertheless abandons the method because he finds his assistants do not practically, for want of attention to details, secure good results at all times. When it is remembered that, after all, the necessary manipulations consist simply in allowing the pads to remain in the fuming-box for a specified time, and in maintaining an adequate supply of ammonia in the saucers or dishes, we are certainly at a loss to discover the difficulty which exists in carrying out the operation as it should be; and we should truly rejoice if all requirements in photography were as easy of fulfilment as these.

Under these circumstances, therefore, he can hardly justify M. Engelmann's condemnation of the method, more especially as we ourselves have also had practical experience of printing with washed paper. If the fuming-box is well arranged, and sufficiently spacious to allow of some kind of sorting of the pads, as also of the entrance of two or three ammonia saucers, no difficulty should arise in working. All the pads should be placed in the box over night, and returned after being once used, a second treatment with ammonia vapour of an hour or two being sufficient to render the pad suitable for further use. With this arrangement, and by the aid of a few spare pads, it is possible to produce good uniform results, and the replenishment of the ammonia liquid every now and then is certainly no very great hardship.

The advantage of doing away with the tedious operation of sensitizing, except at rare intervals, is one not to be despised; and, moreover, the circumstance of thus being

always provided with a supply of sensitive material should be duly considered. The vigour and tone of the finished pictures are likewise fully equal, if not superior, to those produced in the ordinary manner, provided that care be taken to over-print well in the first instance, as the tint is much reduced in toning.

Dr. Vogel, in a communication we publish in another column, also points out the advantages of printing in this manner. He proposes, however, instead of the fuming operation, to introduce into the printing-frame a little powdered carbonate of ammonia. This is rubbed upon a thick piece of cloth or felt, which is placed upon the albuminized paper, being divided from the latter by means of a sheet of filter-paper; and a pad treated in this manner will, according to Dr. Vogel, serve for a whole batch of prints. Seeing that no danger is likely to arise to the negative from the fact of its being separated from the ammoniacal pad by two thicknesses of paper, we think this modification a very good one, and well worthy of trial by silver printers.

ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

TUITION AND ADVICE FOR PHOTOGRAPHERS.—CARBON, SILVER, AND PHOTO-MECHANICAL PRINTING PROCESSES.—MEDALS FOR PHOTOGRAPHERS.—THE VICTORIA CARD.—PHOTOGRAPHY AT THE FORTHCOMING INTERNATIONAL EXHIBITION.—THE PHOTOGRAPHIC SOCIETY OF LONDON.

I WAS interested in reading, in a recent issue of the PHOTOGRAPHIC NEWS, the letter of a gentleman expressing what I believe to be a want very commonly felt amongst professional as well as amateur photographers. I mean the need for some trustworthy instruction. It may be said, naturally enough, that men should acquire a perfect knowledge of any trade or business before commencing its professional practice; but that is just the difficulty. In my last "Echoes," referring to the apprenticeship system as proposed in America, I remarked that the majority of photographers "pick up" their knowledge of their business. Many of them would be glad to obtain instruction before they commence the professional career to which they have resolved to devote themselves; many of them would be glad of such instruction after having commenced business and discovered their deficiencies. But I fear the want will be found very difficult to meet. To make the instruction valuable, it should be given by men of recognized ability and known reputation; and these are usually so fully and profitably engaged, that their services must of necessity be costly, if attainable at all. To suppose that men of such position would call round upon photographers and offer their services is simply preposterous. The smallest honorarium which could be offered to a man of recognized skill and reputation would be (say) five guineas a day; and, whilst this sum would rarely pay him for neglecting regular business duties, it would be a rate of payment which few of those most needing instruction could, with convenience, pay for as many days' instruction as they would require. Doubtless there are many in the profession who would be glad to give lessons at a cheaper rate, but, as a rule, these would not be of the class whose instruction would be in demand. If a trustworthy consulting photographer were accessible, from whom tuition or advice might be obtained, it would often be a boon to the public; but it is more doubtful as to how far it might suit the purpose of any gentleman of skill to accept the position. The advice of the Editor of this Journal is, as its readers know, given freely upon almost every conceivable subject connected with photography, but it would be a boon often to be able to ask a personal opinion upon individual cases—upon the precise details, for instance, of constructing and arranging a glass-house in a given position; upon possibilities of modifying lighting arrangements; upon the condition of some bath or other solution which may be obstinately troublesome, and of which

a sample might be sent for examination. If, when requiring specific information demanding much more time and attention than he can ask of the Editor, the photographer could send his guineas and queries, knowing that, as he pays for the time and ability, he will get value in return from an experienced adviser, the facility for this, as well as regular personal instruction, would be a boon of great value.

I have no intention of opening the closed controversy of carbon *versus* silver printing. But I may, perhaps, be permitted to make an explanation to Mr. Woodbury, who asks what he has done that I should wish to draw him into the controversy? I cannot but think that Mr. Woodbury puts an odd construction on my remarks, when he suggests that they imply that a controversy exists between him and Mr. Edwards. The controversy as first initiated stood thus: Mr. Bovey affirmed that carbon printing was a failure, that it would never supersede silver printing, but that the photo mechanical printing process of Mr. Woodbury and Mr. Edwards, being superior to carbon printing, might eventually supersede silver printing. On the other side, the inferiority of carbon was denied, and as a practical trial of carbon and silver was about to be made to decide one element of the controversy, I suggested that photorelief prints and heliotypes should be produced from the same negatives, since these processes had been referred to as superior to carbon, and more likely to supplant silver printing. Surely there was nothing unreasonable in this; and surely, unless Mr. Woodbury is disposed to repudiate his champion, he should not reject the opportunity of a practical comparative test of the capability of his beautiful process.

The recent intimation of the award of Indian medals to English photographers was not only a gratifying announcement in itself, but it was suggestive, besides, of the enquiry: When is the London Society about to resume the distribution of medals to those who excel at its exhibitions? The last two exhibitions have contained examples of photography such as, I believe, have never been displayed before at any photographic exhibition in this country; but the exhibitors of this unusual excellence have no record of acknowledgment of their triumph. Medals used to be awarded at the London exhibitions; and although we know that the Society has been retrenching, would it not be easy to get up a special medal fund? I fancy that this would be found an easy task, and is one certainly worth consideration.

How is it that photographers in this country have not taken up the Victoria card—I mean, of course, taken up the idea of producing and pushing it? In America I am told that it is a success. In Continental Europe it has been taken up heartily, and will become a success. Is there a single English photographer who has produced a single example? I know a thousand objections can be alleged against it. "A size between the card and cabinet is unnecessary." "It is inconvenient, and involves trouble, and some slight modification of apparatus." "There are no albums for the size." "The public do not want it," and so on *ad infinitum*. When card portraits were introduced, similar arguments were advanced against them. When cabinet portraits were introduced, precisely the same arguments were advanced. It was not until other countries had made the styles successful, and the public, bringing examples from abroad, demanded them, that the photographers of this most conservative land would stir in the matter. In a business like that of the photographer, demand should not precede supply, but supply should suggest and create demand. *Verbum sap.*

Will photography be satisfactorily represented at the forthcoming International Exhibition? It may well be feared that it will not, from the little consideration shown by the Commissioners for photography and photographers. The announcements and information have been

of the most scanty description: even until now photographers remain without any information as to the gentlemen whose *fiat* will decide whether their contributions shall be exhibited or not. According to the graphic account of your correspondent, Mr. Theophilus Middlemitch—I believe I know the estimable old gentleman, and can sympathize with him deeply in the shock inflicted upon his methodical and deliberate habits—photographers do not receive more consideration inside the building than they do out. But, despite all this, I believe there will be a very excellent, although limited, display of English photography in the first of this series of exhibitions.

The chief matter of interest at the societies is the exceedingly satisfactory report and balance-sheet of the Society of London. The system of retrenchment inaugurated some years ago by the late esteemed secretary surrendering his salary and acting as honorary secretary, and which has been carried out yearly with increasing vigilance by the president and council, has brought things to a satisfactory issue. I understand that the Society will very soon be quite out of debt, and will then have a surplus income with which to achieve many good things. Let us hope that it will not waste, say, a hundred pounds, upon foolish collodion committees to test the product of a single maker, and declare it the best without examining any other, as it once did; and that it will not be driven to waste, say, another hundred pounds, on defending its property in the title to its Journal, as it once was; and, in short, that, with the experience of the past, it will not repeat its errors, but will occupy the proud position it should do, of elevator and bulwark, as well as representative society, of the art and its votaries.

AMERICAN CORRESPONDENCE.

DEFEAT OF ANOTHER IMPORTANT PATENT.—A FEW DODGES.

Defeat of Another Important Patent.—What is uppermost in the mind must come first, so I must tell you of another triumph in behalf of the photographers of the United States; namely, the total defeat of the owners of the so-called "Sliding Plate-holder Patent."

In 1855, Albert S. Southwaith, of Boston, obtained a patent for sliding the plate-holder over the field of the lens, so that pictures could be multiplied upon one plate without removing it from the camera. Not content with the profits which his own special contrivance might bring him, if honestly pushed, he joined one Simon Wing, also of Boston, in partnership with him, and they twain proceeded to collect royalty from every fellow-photographer who used any sort of a sliding plate-holder, or any other method of producing more than one picture upon a plate with one lens. Many photographers, frightened at this presumption, at once recognized the claims of their Yankee confreres, and paid up. Not so, however, with all. In their peregrinations they came upon Mr. C. C. Schoonmaker, of Troy, U.S. They made their demands upon him, but did not find him so ready a victim. Possessed of some genius in his own right, he had, years before their patent, contrived a means of doing just what they had obtained a patent for, which fact he brought to the notice of his Boston friends. They were not satisfied, however, and commenced a suit against Mr. Schoonmaker, to collect the royalty they demanded, namely \$500. With most persistent pluck and bravery, Mr. S. proceeded to collect testimony in behalf of his side of the case, and produced evidence so overwhelming—collected both at home, in England, and in France—proving that the complainants were not the original inventors of what they claimed, that his Honour Judge Nelson decided, in the U.S. Circuit Court, in New York, that the claims of the patentees were "invalid and inoperative."

Not content with this, the chapfallen twain appealed from Judge Nelson's decision, and the case was carried to

the Supreme Court at Washington for trial. It there hung fire, awaiting its turn for a hearing, until late last month, when it was argued; and on Feb. 6, 1871, the happy announcement was made that the Supreme Bench confirmed the decision of Judge Nelson. At the announcement of the decision, telegraphic congratulations flew like wildfire from one to the other of the photographers all over the country, for nearly every one of them uses some arrangement or other that would be considered an "infringement" if the decision had been otherwise. As it is, another photographic patent has been overturned and completely laid out, and many thousands of dollars each year saved the fraternity. It is on this account that we rejoice as we have not rejoiced since the defeat of that companion imposition, the famous Bromide Patent. English photographers, who are under the protection of a sensible patent law, can hardly appreciate the feeling of joy this decision gives the American photographer, but I record the defeat in order that they may be glad that no such exactions are made upon them to hamper and to rob them.

A Few Dodges.—How much the usefulness of photographic journals would be enhanced if the practical every-day workers would communicate from time to time such little notes concerning their practice as I am about to give you below. If they would, their editors would not have room to give to discussions pertaining to impracticable matters concerning a few only, and much more good would be accomplished. I never spend a half hour with such a photographer without obtaining some little idea, unknown to me and useful to others.

Now here is an example of what I would like to see a more general voluntary thing on the part of the best practitioners in our art. Mr. Robert Benecke, one of our most efficient photographers in St. Louis, in response to just such a call as the above, sends me a dozen of his "little dodges," which are so useful that I give them for the benefit of your readers. Although some may be familiar with all of them, I will guarantee that they are all new to others. Mr. Benecke says:—

"I give you some of my 'dodges,' which I have been using practically (not fictitiously) in my gallery, and which I found of real benefit to me. I will give them to you just as they enter my mind, and only wish that some of your numerous readers may be benefitted by adopting them in their practice.

"1. When going out viewing, I have found a funnel made of glass or gutta-percha a very unhandy thing to take along. I am using now a piece of good stiff writing-paper, which I twist into the shape of a funnel, and keep so by the aid of a little sealing-wax or gum-shellac. I use them but once, and throw them, when home, into the basket with other silvered paper scraps.

"2. Common printers' ink I find excellent for painting over the sky, &c., in a negative. It never will crack off, but it takes several days to get dry.

"3. When printing large copies it will happen very often that the paper will not be in contact with the negative, but will give us, in spite of the hardest pressure or tufts of cotton you may place behind it, a mezzotint effect in some small places. To have the paper as flat as if it never had been touched by chemicals, I have two frames made of thin board, both of the same size, and a little larger than the negative, and made of pieces about one inch wide—just imagine the wooden frame around a schoolboy's slate. On one of them I have glued a narrow strip of buckskin. Now, when the paper is a little damp yet, lay it between these two frames, the buckskin inside, clamp them together with clothes-pins, and let it get dry. It will be as straight as a drum's head now, and very easy to handle.

"4. In mounting large prints I use a very thin paste all over the back of the picture, and a thick paste only around the edges, mainly to keep the ends from turning up.

"5. For cutting out large prints true and expeditiously, I am using a square board of soft wood and a steel rule—I

had it made in a saw manufactory—with a short piece riveted to it at right angles. Lay the print now on the board, and under the rule; see that the horizon or a perpendicular line comes to lay parallel with the rule, then hold it (print) down by means of a weight (piece of marble) and cut it out. If your board and rule is correct, the print will have been trimmed quite true.

"6. I am using a flat dish for silvering my large plates; twenty-five ounces of silver bath will thus do me for plates 13 by 17. Now, before taking the plate out of the dish, which has been kept in motion by gentle tilting, I turn it over and lay it face down upon the solution, thereby washing off any floating particles from the film, and avoiding pinholes.

"7. For fastening my tubes to my boxes I use screw-rings. A half turn to two of them will enable you to take off the tube in five seconds.

"8. When cutting out stereographs, I mark the two prints by a single stroke of a very soft pencil, on the back, in the centre. Then I cut them apart, hold them up between me and the light, superimpose them, see especially that the horizontal lines coincide, and cut them out. In mounting, observe to have the two pencil marks on the outer edge.

"9. In my plate-holder, for larger views, I do not use glass corners, but four pieces of thick silver-wire, which is just bent a little so as not to scratch the film. The spring on the shutter keeps the plate in its place, and a narrow strip of blotting-paper, doubled six or eight times, through which the lower two pins are pushed, serves to suck up all silver solution, and prevents stains.

"10. A very 'handy' and easy way to obtain relief in the background is, to move a very light triangular-shaped frame, about five by three feet, covered with white muslin, behind the sitter during a part of the time of exposure. A little experience will soon teach you how long to expose it, and how far to move it, &c.

"11. For copying pictures I am using a one-quarter size tube, of which the rack-work has been taken off. This enables me, when copying Daguerreotypes, to push the ground glass to one side or take it out, and also slip out the tube and look right at the picture through the camera-box. Any false reflection is noticed immediately, and can be corrected. For enlarging, say a card picture, to one four by four size, or larger, I reverse the tube by putting it into its opening through the camera-box, and have the back lens now towards the picture.

"12. For taking my 13 by 17 views, I generally use a No. 5 Zentmeyer lens. The stand-box, plate-holder, and tube, I do not think weigh over twenty pounds, for I can carry it easily in one hand. Since I found that a picture taken with the Zentmeyer lens was as sharp ten yards off as one mile—for all practical purposes, I found out the length of focus of the lens exactly, made my box just so long, and use no ground glass at all. My camera is made of light wood, and of a triangular shape, which enables me, for instance, to take a view from a window sideways, where I could not find room for a square box, and makes the box so much lighter. A point aimed at by looking over a mark on top of the box will be right in the centre of the plate, and looking alongside the two sides of the box will give about the angle included in the view."

Mr. Benecke promises to send me a description of his box, and if he does, I will communicate it to you. I can testify to the excellent quality of his work, and I send you some examples of it, which are views of the new bridge at St. Louis, taken during the several stages of its construction.—Yours truly,

EDWARD L. WILSON.

Philadelphia, February 13th, 1871.

IS PAPER A CAUSE OF FADING?

BY W. T. BOVEY.

MR. STOKES has doubtless hit a good nail on the head in attributing to paper a possible cause of print fading. In considering this important matter, however, we must not

confound cause with effect; but as the part played by paper is inevitable in its conditions, and being something more than effect, the verbal difficulty will, perhaps, be best surmounted by an application of those half-tones of logical phraseology, *primary* and *secondary*; the first being attached to sulphur, which is the immediate cause; the latter to paper, which aids the destructive working of that cause to an extensive degree. Paper, as is well known, is composed of vegetable substances, artificially prepared. The materials employed in the manufacture of paper, modern science has made manifold and inexhaustible; but in all instances the first principles are maintained and adopted; viz., the conversion of the vegetable substances into a pulp, by means of suitable machinery. Seeing that water is an element largely used in the making of paper, it needs no argument to show that the chemical condition of the paper depends, to a great extent, on the kind of water employed; and it is not impossible that sulphur might, in some instances, be introduced in combination with lime. We have, however, no good reason to suppose that the papers usually employed in photography contain matter which can impair the permanency of the prints produced thereon; for, as far as time has permitted us to judge, a print well fixed, well washed, and entirely free from that nucleus of destruction, *sulphide of silver*, is as permanent and exempt from fading as can be desired. I have a batch of such prints under test, which, up to time present, have resisted a prolonged exposure to a damp and changing atmosphere. How, then, can it be said that paper is a cause of fading? Briefly I proceed to explain: Paper in its texture is soft and porous; it absorbs fluids as readily as a sponge; therefore, when immersed in hypo solution, the pulp speedily becomes saturated with the sulphur compound, which, being imprisoned in myriads of minute cells, its eviction therefrom is a matter of considerable difficulty, as is fully shown by the prolonged washing necessary, and to which silver prints are submitted subsequent to fixation. A further proof of the fact is given by the easy and thorough elimination of hypo from an albumen or collodion print on glass by a very few moments' effort of washing.

Mr. Stokes has doubtless accurately observed the difference in the time and trouble requisite to eradicate hypo from paper and from pictures on rigid supports, and again he hits a good nail on the head in his suggesting the adoption of a paper made impervious to moisture. I have made several attempts in the direction indicated, but, unfortunately, my experiments have only shown that a law analogous to the physical rule of compensation applies materially to the chemical working of the paper, when the latter is enabled to refuse water.

The toning properties of a paper depend greatly on its porosity and absorptive capability; hence a plain salted paper tones the most rapid. If coated with diluted albumen, the prints tone somewhat slower, yet, comparatively speaking, they darken rapidly. As we thicken the albumen, toning grows more and still more sluggish. These variations must be attributed to two causes: first, the resistance offered by the albumen; second, the comparative degrees of free silver, which vary in each instance, having its maximum in a plain salted paper print, its minimum in one produced on a strongly albuminized paper. A patent was taken out some years ago (I believe the kind of paper is still in the market) for rendering paper impervious to water by means of a coating of india-rubber previous to albuminizing; but, as far as my experience went with the paper, I found that the image, though admirably delicate, could not, as a rule, be toned beyond an agreeable brown; and my own experiments seem to confirm the statement as a fact, that similar results to those just described follow the use of any foreign substance for the purpose of filling in the pores of the paper prior to albuminizing. The reason why is obvious. When the porous texture of a paper is blocked with matter that takes no part in the construction of the

photograph, the top stratum is, perforce, very thin (you cannot pour albumen on like collodion is applied); the building material that forms the picture is, therefore, very scant, and a delicate, but not always sufficiently vigorous, print results. Such a paper coated with collodio-chloride would be simply perfection, always premising that the collodion is one possessing stout body. The fuller the body of collodion, the richer the resulting picture, because, under such condition, an ample supply of building requisites are provided. I should like to see in any way clear to the possibility of using collodion exclusively in the production of silver prints. The pictures are so richly transparent, so beautiful and delicate, no albumen print can equal them in beauty, and nothing can promise a more extended degree of stability. Having given away all the examples I produced immediately subsequent to the introduction of the process, the Editor is, perhaps, in a position to state whether the prints I sent him at that time retain their pristine purity of colour. At all events, let the case rest as it will, the prints alluded to received only a few minutes of washing under a running tap.

There are, I fear, adverse conditions that make it improbable that collodionized will ever supersede albuminized papers, the former being unavoidably expensive, and, in some respects, very troublesome to work with and prepare. The possibility might be conjectured of preparing a paper in such a way as to render it impervious to water, yet accessible to silver and the other materials required in the production of the picture. I admit the possibility, but, unfortunately, the water-proof nature of such paper would make it impervious to the action of the fixing agent. In all my numerous experiments in this direction, I have found that whilst silver readily penetrates wherever a chloride salt can be introduced, hypo can only act upon the surface of an impermeable substance, and, therefore, cannot follow the silver that lies beneath; hence the picture continues to darken when its surface is deprived of reducing tendencies.

With this view of the matter, I fear that Mr. Stokes's well-applied nail cannot be clenched. Until we are in a position to do away with silver printing (*and the sooner the better, say I*) we must endeavour, by care and caution, to make our prints as permanent as possible. Were it practicable for the photographer to retain prints in an unmounted state for a month, he need send out no prints destined to fade, as the traces of coming decomposition are soon made evident; but as customers are generally in a hurry for their pictures, the only course to avoid print-fading is to understand the nature of the causes, and, as far as possible, to avoid them.

[We have examples of collodio-chloride prints by Mr. Bovey, and also by ourselves, which have been in our possession six years without any sign of change.—ED.]

INSTANTANEITY.

BY STEPHEN THOMPSON.

THERE is a latent desire running through the minds of most photographers—unshaped and unembodied, it may be, but still felt in some dim way, that has not yet found means of expression—to enlarge the somewhat restricted domain or sphere in which photography lives, and moves, and has its being; in short, the peaceable extension of our frontier line in the region of art; which, happily, in this case, does not necessarily involve any annexation of the territory of our neighbours.

Many feel, after some length of practice, more particularly if they have ever at any time been accustomed to use the pencil, which knows no limitations but in the imaginative power of the limner, a sensation of being "cabinied, cribb'd, confined," to a degree of weariness. At first all is *couleur de rose*; but at length the caged feeling comes. We pace, in imagination, up and down our domain, but soon—

"Shades of the prison-house begin to close,"

and we earnestly scan the horizon on every side, seeking to find some avenue, some outlet, where we may breathe a freer air, and attain a nobler, fuller life. In what direction may we hope to find it? Colour? No, not yet, if ever may we hope to clutch such an intangible beauty as colour! Why sigh for the unattainable? As well bay the moon, or spend our days and nights in seeking the elixir vitæ or the philosopher's stone. That is not the path for the transmutation of our labours into precious metals. But there is one direction, within the bounds of possibility, in which it may be sought, and it would enlarge our sphere of operations in an immeasurable degree; and that is, *absolute instantaneity* on large plates, say plates 18 by 16, a size sufficiently large to make pictures for hanging.

At present we are confined, in a great measure, to one aspect of nature only—nature in repose. The peaceful landscape, the stately ruin, on which time feeds like slow fire upon a hoary brand, are ours; but life, motion, and all its poetry; nature—living, warm, breathing, pulsating nature, with her April face and her April eyes, her stormy passions and her sudden calms; the power and mystery of nature, not only her outward form, but her beating heart—lies just beyond our domain. Walk through one of the annual exhibitions of the Royal Academy, specially noting how many of the subjects would have been within the reach of photography had it but that other step added of absolute instantaneity.

Here are "Fishing-boats coming in," canvas (say) 24 by 18 in.; time, early morning. Their tawny sails, wet with spray, shine brightly in the sun. Around the bluff bows of each seamed and weather-stained craft is a fringe of cloven foam. They plunge and dip cheerily, as with joy of relief after a night at sea, and as they ground one by one on the shingly beach, a picturesque group surrounds them, and all is bustle and animation. What is the condition that prevents its delineation by photography, but instantaneity? More sensitiveness to colour would help, but the whole scene is evenly lighted in the still low-voiced sun, and it is of only secondary importance.

Here another: a pilot's lugger-boat going off through the surf in half a gale to the homeward bound Indianan in the middle distance.

Again: a rain-swirl amidst Highland scenery; broken patches of sunlight lighting it up here and there, such as may be seen almost any day among the Grampians, or the Cuchillin hills.

Or stand with me on an antique wooden balcony at the corner of the market square, or in front of the gothic cathedral—often the market square too—of some old continental town, say Boppard, or, better still, one of those in the west of Normandy (time, seven A.M.), and watch the busy picturesque scene, and wonderfully picturesque costumes of the ever-moving crowd, before a background made on purpose—old gabled houses, and a richly-carved but ripe and crumbly old medieval civic or ecclesiastical facade—and then feel what instantaneity would do. A small stereo might be got of a bit of it, or a larger bit if you submit to the reduced size of the wide-angle lens, but at best it is only a microscopic reduction of the scene, for which you might have cared if you had not seen the original. Then, too, that golden shadow, luminous with softened detail, which slopes right athwart it in the early morning sun, would probably have been represented by a black outline, and no more.

Yet, again, let us regard the pathos that dwells around a lone rugged cliff washed by the restless sea, now crooning its soft sad song, and now dashing its white delicate foam in wild caresses high up the patient rock, and now retreating coy, while sea birds wheel around with hoarse plaintive cries, and large billowy clouds sail by in solemn procession. What has instantaneity to say to that?

But nature knows no pause. She is busy making pictures everywhere. Why should we be shut out from half her joys?

We know it is not in the representation of the physical phenomena only of nature that the truest art dwells, and we also know that at least twenty painters give us that only, for one who can reach the mystery, the pathos, and the suggestive human expression, that underlies all this.

Turn to another class at the same exhibition, and note how many of the figure subjects are barred by the same conditions. Surrounding accessories being within the scope of photographic delineation, some happy idea, some odd bizarre incident, depending for its point chiefly on facial expression, is the difficulty. It is often possible to get the expression depicting or lighting-up the incident or idea, even when there are two or three actors in the scene; but to *preserve it*, never. In this sense

"How fleet is a glance of the mind,
Compared with the speed of its flight!"

Perhaps enough has been said to indicate the direction in which progress may be sought; the means thereof must, of course, come by improved optical or chemical conditions, or both combined. This part of the subject is much too extensive to enter upon now; but with regard to the chemical portion of it, I am not aware that an exhaustive series of experiments with all the known agents has been attempted having this sole object in view, though there has been much invaluable and interesting, yet desultory, work done.

It is very desirable to stimulate efforts in this direction. "Nothing is too wonderful," said Faraday, "if it be consistent with the laws of nature;" but here there is nothing required but improved conditions in means which we already possess. That it will come is a matter of certainty. Something more than indications of it might be seen in the seascapes of Mr. Robinson at the November exhibition. There can be little doubt but that it is worthy of the gravest attention, both because it is quite within the bounds of possibility, and that it would yield a large access of territory to photography.

ON THE SENSITIVENESS TO LIGHT OF THE RED FERRIDCYANIDE OF POTASSIUM.

Communicated from the Photographic Laboratory of the Royal Industrial College at Berlin.

BY DR. H. VOGEL.*

It is a known fact that the solution of red ferricyanide of potassium is easily decomposed, yellow ferrocyanide being formed, together with a blue precipitate of Prussian blue. Gmelin, the discoverer of the red ferricyanide, had already observed this, and it is, moreover, known that organic substances have the effect of materially hastening the decomposition. It would appear, however, hitherto to have escaped the observation of investigators that the action of light plays an important part in this reaction; this I have lately proved by a series of experiments which I will here briefly enumerate.

If a solution of one part of ferricyanide of potassium in ten parts of water be submitted to the action of light, there will be observed, after an exposure of a few hours, a dark colouring of the liquid easily to be remarked when compared with a solution which has been preserved in the dark. Whilst a fresh solution of this kind yields, on the addition of oxide of iron salts, no precipitate whatever, the exposed sample exhibits a blue precipitate, no doubt Prussian blue, and with salts of uranium yields the well-known brown colour of ferrocyanide of uranium. The solarized solution, moreover, shows also the reactions of the yellow ferrocyanide of potassium, so that it may be inferred a reduction has been caused by light. How sensitive this solution of ferricyanide of potassium is to light may be inferred by the statement that an exposure of thirty seconds in sunlight suffices to form yellow ferrocyanide, the presence of which may be proved by means of chloride of iron solution. If the expo-

* *Photographische Mittheilungen.*

sure is continued for some time a small quantity of a bluish black precipitate is thrown down in a similar way as when the spontaneous decomposition of the red ferricyanide of potassium occurs on the presence of organic substances.

In yellow light I have been unable to observe any decomposing action of the red ferricyanide solution; neither have I been successful in discovering any action in the salt itself, although it is nevertheless my opinion that a change does actually take place when the salt is exposed to intense chemical rays during the summer months.

This reaction of light upon ferricyanide of potassium solution I have endeavoured to utilize in the production of photographic pictures. Some paper was floated upon a ten per cent. solution of ferricyanide, and dried in the dark. Placed under a negative in the pressure frame this paper became impressed, after a short exposure, with a weak image, which, when dipped into a solution of chloride of iron, became of a vigorous blue, the yellow ferrocyanide produced by the light being transformed by the chloride of iron into Prussian blue. Similar pictures were obtained, but in a totally different manner, by Herschel in 1840, by employing the chloride of iron as the sensitive material, and treating the subchloride formed by exposure to light with the red ferricyanide of potassium; thus producing an image in Turnbull's blue.

If, instead of treating my faint image in an oxide of iron solution, I had placed it in one of oxide of uranium, a precipitate of ferrocyanide of uranium would have been produced, and thus a picture of an agreeable brown tint obtained.

By exposing ferricyanide of potassium paper under a negative for a very lengthened period, a pale bluish black image is produced, which may be easily fixed by simple washing in water.

In practical photography these reactions are at present of little value, seeing that the durability of cyanide compounds is questionable; but for the manufacturing chemist they are of significance, and he will do well to preserve his red ferricyanide of potassium solutions sheltered from solar action, and to evaporate and crystallize them only by caudle or lamp light.

The analytical chemist may learn therefrom to preserve his solutions in yellow bottles, it being presumed, of course, that the same have been in the first place prepared with perfectly pure water. Very frequently distilled water contains organic matter, and this will alone cause a decomposition of the compound when preserved even in the dark. It is very probable that several other compounds which are stated to decompose spontaneously may be found to be sensitive to light in the same way as the red ferricyanide of potassium.

PHOTO-KALEIDOSCOPIES.

A CORRESPONDENT, signing himself "An Old School Photographer," sends us an old journal containing the following article, remarking that, as the application of photography to the kaleidoscope has been more than once suggested as a novelty during the last few years, the reprinting of this article, which appeared in an American journal signed E. K. Hough, more than a dozen years ago, may interest many readers.]

Every photographic operator knows the value of ways and means for keeping his visitors in good humour while compelled to wait their turn for a sitting. Without such means they often get expressions of anxiety and impatience that interfere sometimes seriously with successful results. With this thought, rooms are often richly furnished to give the soothing influence of luxury and ease. Also the walls are hung with pictures to charm the attention into self-fancifulness—which is the best possible mental condition for a perfect likeness, could it be always attained. But these pictures too often are only a monotonous series of faces with but little variety of expression or position, with few

elements to interest beyond a passing glance as specimens of the artist's success in chemical effects.

Landscape views have a large variety of objects, and, when well executed from interesting scenery, have much more power to engage attention than mere portraits can have, and it seems strange that so few adorn our galleries. But, best for the purpose named is something that contains facility for new combination and variations at the option of the observer, and of course it were always better that it have some relation to the photographic art. That which will meet all these requirements most fully is undoubtedly the stereoscope, with a large variety of interesting views, for none other can show so strikingly the wonderful capabilities of the art.

But as they are too rarely found, especially among country operators, and, moreover, are slightly expensive, I wish to suggest something trifling, yet an amusing substitute, which can be readily constructed by any artist in his leisure moments, and almost without cost. We all remember the interest with which we have watched in our boyish days every varying scenery of the kaleidoscope.

We are but "children of a larger growth," and the toys of childhood are often reproduced in manhood, only on a larger and more expensive scale.

I will give in a few words my plan for the construction of a photo-kaleidoscope.

With a couple of strips of black glass—which can be obtained of any suitable length from the stock dealer—a few strips of cardboard and fancy paper, a tube can be constructed in an hour. Then, in place of bits of glass having no charm but colour, I would substitute small pictures on glass—either common ambrotypes, or transparencies produced by printing from negatives on collodion. If to be viewed by reflected light, they should be coloured, coated with benzine or collodion varnish, and placed on a clear glass fitted in the bottom of the tube, and a dark opaque ground placed behind. In this arrangement openings should be left just above to illuminate them.

With the transparencies, the sides must be closed and the light admitted at the end through a fine ground glass or oiled paper, and the pictures should be coloured with brilliant transparent colours. The figures should be full-length, quite small, and very sharp, on square or oblong plates, and so arranged between the glasses that hold them in their place that, while having a free sliding movement singly, they cannot lap over each other. A moment's consideration will convince that when well constructed and filled with figures in dancing, pugilistic, clownish, and similar attitudes, the thousand shifting combinations will present many comical and amusing phases, especially if they have a local interest. And if in any room the tedium of "waiting for a picture" (to which "waiting for the waggon" is no comparison) should be somewhat relieved, my purpose will be accomplished.

Correspondence.

PROFESSIONAL INSTRUCTION FOR PHOTOGRAPHERS.

DEAR SIR,—I was much amused at the frank confession contained in the letter of "H. S." in last week's NEWS, and also at the funny idea of a "gentleman of established reputation," &c., calling at the various studios and soliciting patronage in the way of giving instruction. It appeared to me like reversing the order of things, as we generally find application made from the other side; and, indeed, the last place expected where such instruction would be needed would certainly be at one of the "best studios" in such a town as Brighton.

I cannot tell what the feelings of others would be, but I must confess that if I were the principal of such a studio, &c., I should feel offended at such a proposition, and not "receive them with open arms and hearty welcome." I quite doubt that "such a method would be very desirable, or an improve-

ment to portraiture." I would rather suggest that before possessing the superior studio, the more important provision should be secured of ability to conduct it. Anxiety to get good results is laudable, but that alone will never enable anyone to compete with superior talent, or to keep pace with the times.—
Yours truly,
J. B. S.

PAPER IMPERVIOUS TO MOISTURE.

DEAR SIR,—So far from the subject of Mr. Stokes' letter in last week's NEWS not being worthy of notice, I think it of considerable importance; indeed, it is one which has often engaged my thoughts. I think there would be great advantages if the paper, previously to being albuminized, was made impervious to moisture. The hypo which we are at such pains to wash out of the paper would not be permitted to get in; there would also be an advantage in the mounting of prints, as the expansion of the paper by the application of glue, starch, or any of those substances requiring water as a solvent, would be prevented; and the cockling of the mounts when the prints are dried would be avoided; probably it might also prevent fading caused by the action of any injurious substance in the mount itself.

Mr. Stokes asks whether the preparation of such a paper is "an impossibility"? I think not, for the following reason: many years ago I had occasion to colour some lithographic views printed on plate-paper, which absorbs moisture rapidly, so that it was necessary to apply a size to prevent the water-colours sinking into the paper. The late W. Day (founder of the well-known lithographic establishment in Lincoln's Inn Fields) was kind enough to give me a recipe for such a size, which, when properly made, answered the purpose well; but on one occasion I accidentally put in an excess of one of the ingredients, and the consequence was, that the paper was made so hard and non-absorbent that a print could be coloured and then the whole sponged off and left as though no water-colour had been applied at all. From this I infer that paper can be made impervious to moisture.

The question, of course, arises, whether the application of such a size would be injurious in the printing? From its composition I think not, but if Mr. Stokes would like to have a copy of the recipe, I shall be happy to furnish him with it; or if you, Mr. Editor, would think it worth while to publish it, I shall have pleasure in sending it for that purpose.—Yours truly,
WM. MONKHOUSE.

Lendal, York, February 27th, 1871.

[We shall have pleasure in publishing the recipe in question.—ED.]

COPYRIGHT PROPERTY IN NEGATIVES AND PRINTS.

SIR,—With reference to the letter of "Colonist" in your last issue, allow me to correct an error in the first paragraph, which, perhaps, is only a slip of the pen. I have never asserted that a portrait negative (taken in the usual way) is the *copyright* of the photographer, which would be absurd. I have only said that it is the *property* of the photographer.

As regards surveyors and reporters, their cases are scarcely analogous, because their rights are not defined by Act of Parliament, as are the rights of artists and photographers.

"Colonist" asks you for advice how to obtain protection for an original design. Allow me to inform him that he can do so by registering it at the Government Registration Office at Whitehall. He can do so through the post without necessity for personal attendance. Registration at Stationers' Hall is needless for anything other than paintings, drawings, and photographs, excepting foreign works of art under the International Act. English lithographs, and similar works, are therefore registered under Talbourn's Act; but such registration affords no protection against piracy, and simply brings grist to the mill of the Stationers' Company. If a principle is involved in "Colonist's" invention, letters patent must be taken out.

Mr. Foster is a gentleman for whom I have the highest respect, for it is greatly owing to his exertions that we have a Copyright Act, and I think our brother photographers would have been grateful had he been pleased to express his opinion respecting the right mode of construing the Act. Instead of so doing, Cassanira like, he utters a prophetic warning to our brethren "not to rush hastily into a course of action," which they will do well to consider. At present they rush hastily to

register at Stationers' Hall, without first ascertaining what they have to register; in consequence, as recent events show, they find "they are landed in an awkward position." Mr. Foster advises them "to seek the opinion of some qualified legal adviser." Good advice, no doubt; but as Diogenes required a lantern at mid-day to assist him in his search for an honest man, so does the photographer require an aid in his search for that *rara avis in terris*, a lawyer with knowledge of the law of artistic copyright. Before he can have his advice, he must follow Mr. Glasse's instructions anent cooking a hare: first catch the lawyer.

Why so few lawyers know anything of artistic copyright law is easily explained: beyond the miserable police court prosecutions, there have been no cases. The Act has been in force eight years, and, during that time, no artist has appealed to it for protection. A few prosecutions have been instituted by photographers, and many by "an eminent publisher." It therefore follows that subsequent to the commencement of the Act, the producers of copies of works of art, and the forgers of signatures, ceased from their nefarious labours—or, that artists value their newly-acquired rights so lightly that they do not think it worth while to enforce them. The latter alternative I think to be correct, for copies and forgeries still appear on the walls of West End auction rooms as frequently as before the passing of the Act.

Whether my notions of copyright law would provoke a smile from lawyers I do not know; but I can say the notions of lawyers upon copyright law have certainly provoked a laugh from me, and I think the same effect would be produced upon Mr. Foster or Mr. Blaine if they were brought under their notice. I once heard an eminent lawyer express an opinion that all photographs were *copies*—it was not the late Lord Chief Baron who uttered it—and I think it calculated to make Mr. Foster smile, to say nothing of Mr. Robinson or Mr. Rejlander. Another eminent lawyer stated that registration of a work of art was only necessary when the proprietor for the time being wished to prosecute for piracy. That opinion, I think, would make Mr. Blaine laugh, seeing that he has always been an advocate for the registration of all copyrights. Another learned gentleman expressed an opinion that no person was aggrieved by a registration unless he had a title conflicting with the title of the person registered, overlooking the fact that where copyright was non-existent there could be no conflict of title.

I think I have said enough to show that the opinions of learned lawyers are not always to be relied upon. The law of artistic copyright is of recent origin, and there is nothing in it to puzzle an ordinary mind having a little knowledge of logical rules.—I am, sir, your obedient servant,
J. CUNNINGTON.
London, Feb. 28th, 1871.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.

REPORT OF THE COUNCIL—continued

THE report of the Council concludes with obituary notices of distinguished deceased members.

Obituary.

SIR FREDERICK POLLOCK, BART., who for nearly fourteen years held the office of president of this Society (in succession to the late Sir Charles Eastlake) died at the end of August last, in the eighty-seventh year of his age. During this comparatively long period, Sir Frederick was active in promoting the interests of the Society, and in presiding over its meetings, notwithstanding the many claims upon his time imposed by his high official position of Lord Chief Baron of the Exchequer. A graduate of the University of Cambridge, and Senior Wrangler in the year 1806, the late president associated himself with several of the learned societies, and was elected a Fellow of the Royal Society on the 29th of February, 1816.

In his opening speech (April 1855) the late president predicted a glorious future for photography, and referred to the varied objects and applications of the art, laying stress on the value of its faithful and imperishable records. Later, in 1866, when distributing the medals awarded to several distinguished members of the Society, the president did not hesitate to institute a comparison between the benefits conferred by the discoveries of steam navigation and the electric telegraph and those afforded by the improved processes of photography. The first two in-

ventions had, it was true, the effect of annihilating time, and so were commercially invaluable; but the productions of the photographic art were unerring, historical, and especially attractive as addressing themselves to the sympathies of all mankind. Sir Frederick concluded his speech with some admirable remarks on the value of efforts made in the research of scientific truth as contrasted with the time and labour sometimes bestowed in eliciting the truth from statements made in courts of law. As evidence of the high appreciation entertained by the late president for the post held by him in connection with this Society, it is only necessary to quote a few lines from his letter of resignation, dated 8 A.M., 16th November, 1868. Sir Frederick says:—"Having now reached the eighty-sixth year of my age, and my health requiring that I should abstain from evening meetings, I feel that I can no longer discharge the duties of president of the Photographic Society; I therefore through you (Mr. Durham) place my resignation in the hands of the council, regretting much I am no longer able to hold a situation so honourable, and which afforded me so much pleasure and satisfaction, by bringing me into communication with some of the most enlightened scientific and practical men of the age."

REV. JOSEPH BANCROFT READE, M.A., F.R.S., may be described as one of the founders of the art, and was a contemporary of Sir Frederick Pollock in respect of having been elected into the council on the same day as the late president. As far back as 1837 Mr. Reade obtained enlarged representations of natural objects by the agency of the solar microscope, the images being formed upon paper impregnated with common salt and nitrate of silver, and afterwards washed with infusion of galls; and two years later (April 1839) a collection of these so-called "Solar Mezzotints" was exhibited at the *soirées* given by the Marquis of Northampton and by the Royal Society. Without laying claim to the discovery of the latent image, Mr. Reade obtained these results, and fixed his pictures with hyposulphite of soda, other experiments having been made with iodide of lead on paper and card similarly treated. Mr. Reade's first communication to the Society was read on the 1st November, 1855, and entitled, "On the Use of Gutta-percha as a Substitute for Glass in the Practice of Photography." This was a proposal to use a film of gutta-percha as a kind of substratum, on which the collodion was poured, and the process carried out as usual, a glass plate being temporarily employed, and benzole resorted to as a solvent for spreading the gutta-percha. The finished negative was then stripped from the glass, and preserved between folds of paper until required to be laid in the printing-frame. By a singular coincidence, Mr. F. Scott Archer had just previously secured a patent for the same mode of proceeding, which has never, however, owing to the alterable nature of the gutta-percha, been successfully adopted. Mr. Reade took an active part in advocating the "moving focus" system of portraiture introduced by M. Claudet; and, lastly, was the means of bringing to the notice of the Society a discovery of Sir David Brewster, relative to the stereoscopic effect apparent in the Chiment pictures, lithographic representations of which are to be found in the eighth volume of the Society's Journal. The Rev. J. B. Reade was successively appointed vicar of Stone, near Aylesbury, and rector of Bishopbourne, near Canterbury. He was elected a Fellow of the Royal Society on the 8th of February, 1838, and at the time of his death was President of the Royal Microscopical Society. Of this Society he was vice-president, and regularly attended the meetings until April last, after which he was prevented from coming to London by the illness which proved fatal on the 12th December, when in the seventieth year of his age.

MR. THOMAS ROSS, son of the late Andrew Ross, succeeded to his father's business as optician in September, 1859, and was for many years a member of this Society. He took an active part in raising contributions in aid of the Archer Fund, and has, at various times, addressed the Society on the early history and construction of lenses for photographic use. Mr. Ross's Uniovorsal Binocular Camera was described and figured in the Journal of October, 1862. He died somewhat suddenly on the 16th December last.

The following are the officers for the ensuing year:—

PRESIDENT.

James Glaisher, F.R.S., F.R.A.S.

VICE-PRESIDENTS.

Hugh W. Diamond, M.D., F.S.A.

Arthur Farre, M.D., F.R.S.

R. J. Mann, M.D., F.R.A.S., F.R.G.S.

TREASURER.

Henry White.

MEMBERS OF COUNCIL.

John Anthony, M.D.

Francis Bedford.

Valentine Blanchard.

J. H. Dallmeyer, F.R.A.S.

T. Sebastian Davis.

W. England.

Peter Le Neve Foster, M.A.

Talk in the Studio.

ALUM IN THE PRINTING BATH.—Mr. Anthony says, in the *Bulletin*, that he still continues the use of alum in the printing bath. He adds: "We now confidently recommend it to photographers. By its means we have reduced the strength of our silver to thirty-five grains, fuming to five minutes, toning to perfect ease, with the least consumption of gold. All tones from brown to purple blue can be obtained, and the prints have all the force and richness attainable by any process."

THE SCIENTIFIC PRESS IN PARIS.—The majority of the scientific journals published in Paris were suspended during the siege. We understand that some are already making preparations for recommencing their issue. M. l'Abbe Moigno states that on the 1st of March he will resume the publication of his journal *Les Mondes*. A portion of the Abbe's library was destroyed by a shell.

INTERNATIONAL EXHIBITION OF 1871.—We understand that during the week ending the 25th of February paintings, sculpture, engravings and photography, architectural designs, tapestries, carpets, embroideries, designs for decorative manufactures and reproductions, also nearly 2,000 objects of pottery, specimens of woollens and worsteds, and educational appliances, making in all a total of about 3,500 objects, were delivered at the Exhibition galleries. Foreign objects arrived from Belgium, the German Empire, Portugal, Russia, Spain, Hongkong, and Tunis.

FOREIGN PATENTS IN AMERICA.—Inventive skill, and enterprise in applying it, appears to be more active in Great Britain than in Continental Europe, as may be gleaned from a comparison of the patents applied for in the United States' Patent Office, which, during 1870, granted 13,321 patents out of 19,176 applications. Of the patents so granted, 349 were to subjects of Great Britain, 89 to Frenchmen, and 206 to all other classes of foreigners.

FRENCH PHOTOGRAPHERS AND GERMAN SITTERS.—The Special Correspondent of the *Daily News*, writing from Paris under date of February 27th, says:—"The French are always very intense in their national likings and dislikes. It is terrible to see their hatred of the Germans at present. I have recently told you that no Germans will henceforth be employed in Paris—that they will be excluded from clubs—and that the French loathe the idea of modifying the terms of their Treaty of Commerce with Prussia and with the Zollverein, not simply as a question of money, but because they wish henceforth to have nothing to do with their enemies, upon whom one day they will take a fierce revenge. I have been reminded of all this by some English friends who went on Sunday to a photographer. Photographers here do a great deal of business on Sundays if the weather is fine. The people are generally in their best clothes, and like to be photographed, perhaps, for lack of talk. My friends went to a very famous photographer on the Boulevards; but their accent betrayed them—they were evidently foreigners—perhaps Germans. "Are you Prussians?" asked the photographer; "because if you are, I cannot take your photographs." His visitors made their nationality evident by the production of sundry passports, and then at last, his patriotic soul being satisfied, he found it in his heart to take their portraits."

NOVELTIES IN PORTRAITURE.—Our correspondent, Mr. Jeffries, to whose scroll portraits, which he has styled "Effeotographs," we called attention, mentions some other novel effects which find favour with customers. In one, the portrait bust, from life, is printed upon a pedestal produced by masking, giving the effect of sculptured bust. In another, the picture is surrounded by a rustic frame-work, also produced by masking and a little aid from the pencil. Mr. Jeffries is trying to produce masks in which the necessary lines or shading will print through, so as to render the pencil unnecessary; and he thinks he will succeed.

MICROSCOPIC PHOTOGRAPHY FOR PIGEON POST.—A Paris correspondent of the *Daily Telegraph* says:—"I was much interested yesterday in an explanation of the pigeon system kindly given to me at the Central Telegraph Office. The microscopic telegrams sent from Tours were at first printed on thin paper by the ordinary system of photographic reduction; but the paper was too heavy—a pigeon could carry only five of the little sheets, though they measure no more than three inches long and two inches broad. To get over this difficulty the despatches were photographed on pieces of collodion of the same size as the paper, each little bit containing thirty columns, and averaging 20,000 words—that is to say, about the contents of thirteen leaded columns of a London newspaper. From fourteen to eighteen of these tiny leaves were put into a quill and tied to a pigeon's tail, several copies of the same leaves being sent by different pigeons, so as to diminish the risk of loss. When the bird reached Paris the quill was immediately forwarded to the telegraph station, where the leaves were read through a microscope to a clerk, who wrote out the despatches for each person. But this was a terribly slow process; it permitted the employment of only one reader and only one writer, which was insufficient for copying some 30,000 telegrams of ten words each. So, after a few days, the leaves were successively placed in a large microscope, to which electric light was adapted; and the magnified image of each leaf was projected on a white board, from which it was copied by as many clerks, taking a column each, as could manage to get sight of it from the writing table. This, however, was still too slow, and the final improvement was invented. Instead of throwing the image on the white board, it was photographed straight off upon a large sheet of collodion; direct positive proofs being obtained, without any intervention of a negative, by the substitution of black for white, and *vice versa*. The collodion sheets were cut up, and the pieces were distributed to a hundred clerks; so that all the cargo of a pigeon was copied and sent out in a single day. The explanation which I received was accompanied by a practical illustration of the working of the process; and when I left I was presented, to my very great satisfaction, with an original pigeon despatch of the 11th of November. I shall carefully preserve that strange little memorial of the siege."

THE ACTION OF LIGHT ON SULPHUR.—Yellow phosphorus is changed into red phosphorus by the action of light. The observations of Lallemand, communicated to the Paris Academy, show that light affects sulphur in a similar manner. His report to the Academy is as follows:—"When a concentrated solution of sulphur in sulphate of carbon is exposed to the concentrated light of a lens, yellow sulphur will be thrown down in a few seconds, the liquid becomes turbid, and small particles of sulphur will collect on the bottom, which are distinguished from the original sulphur by no longer being soluble in sulphate of carbon. Light which has passed through a solution containing sulphur shows remarkable changes in the spectroscope. All the rays between G and H and the extreme violet spectrum have disappeared completely."—*Mittheilungen*.

SELLING INDECENT PHOTOGRAPHS.—On Thursday week police-constable Murgatroyd caught John West, a man minus a hand, selling an indecent photograph to a young man in Bridge Street, Bradford. He took West into custody, and in his possession was found a number of other photographs of a most objectionable character, prisoner apparently doing a trade in these vile productions. A "gallant show," belonging to West, had been left at the Midland railway station, and on a revolving apparatus inside the box were coloured photographs, equally disgusting as those found on his person. West was brought up at the Borough court on Friday, and was sent to prison for one month.

PHOTOGRAPHING UNTRIED PRISONERS.—At the recent Middlesex Sessions a special report was presented from the

Visiting Justices of the House of Detention as to the taking of photographic likenesses of prisoners for the information of the police. It was merely a reiteration of the objections they had expressed on the last county day as to taking the likenesses of persons waiting their trial, who were, until convicted, supposed to be innocent of the charges preferred against them. They had fully re-considered the subject since the last county day, and, having examined it in all its bearings, on constitutional grounds they saw no reason to depart from the opinion they had expressed in their former report. Mr. Sharpe moved the adoption of the report, and said there was nothing in the Act of Parliament to authorize the magistrates of this country to compel unconvicted persons to have their likenesses taken. After some discussion the report was received and adopted.

To Correspondents.

ADVICE TO CORRESPONDENTS.—We are at all times glad to advise our readers on any subject connected with the art upon which information can be given in this column; but to enable us to do so with efficiency, and without unnecessary waste of time and space, it is desirable that a few conditions should be observed by correspondents. All questions should be stated clearly, and written legibly on sheets of note paper, small scraps of paper and sheets of foolscap being equally unsuitable and inconvenient. Where several questions are asked, they should be kept distinct and numbered. Where processes and formulæ have been stated in our pages, it is better for correspondents to refer thereto than to request us to do so, as we cannot, with fairness, occupy space by repeating formulæ which have once appeared, merely to save a little trouble to individuals. Correspondents should use distinctive names or initials: such signatures as "A Subscriber," "An Amateur," and others of a general character being often adopted by a few correspondents in the same week leads to confusion.

J. MALEB.—The legality of copying a photograph entirely depends upon the circumstances. If the proper steps, in accordance with the statute, have been taken for securing the copyright in the photograph, it is illegal to copy it, and you would be liable to the penalties for making a copy. There is no method of ascertaining whether the photograph be copyright or not without examining the Registry at Stationers' Hall, and ascertaining that all conditions have been complied with. The absence of any intimation on the photograph of its copyright character is no guide for your action, so that you are in danger in copying any photograph unless you have definite knowledge that it is not copyright. 2. The material used for making the bellows of cameras is leather lined with black calico or black linen. We believe that the leather is that generally known as *skiver*, which is a split sheepskin. You can probably obtain a bellows-body of the material to make one of some of the camera-makers whose advertisements you will find in our pages. 3. The copying-camera to which you refer was described by the maker; we cannot give you any fuller details.

TREBLA.—You will be able to obtain of a photographic dealer, or of a dealer in chemical apparatus, vessels made of porcelain expressly for boiling solutions, and so annealed as to stand fire. With care, also, you may safely boil a bath in a Florence flask. Ordinary glazed saucepans are not necessarily suitable; the glaze may be of various substances; but it would be difficult for you to ascertain what yours is, or what contamination the silver bath may have received. 2. We cannot, therefore, tell you what the remedy may be. The small, needle-like crystals are most suggestive of iodide of silver, which it is quite possible you may not have eliminated. 3. Acetic acid should not be added to the bath. Some operators use it, but its use generally involves many troubles, and the instability of the bath. 4. When acetic acid has once been added to a nitrate bath it is almost impossible to eliminate it. If you neutralize it with an alkali—say carbonate of soda—acetate of soda is formed, but this is quickly decomposed, acetate of silver being formed. This tends to give density, but it often causes insensitiveness and an unstable condition in the bath. 5. There are various modes of making the paper keep well for a few days after sensitizing. The addition of a little sugar to the bath aids in this. Washing the free nitrate off aids materially. If you only wish the paper to keep a day or two, dry rapidly after sensitizing, and keep the paper dry and protected from the atmosphere, either by rolling up tightly and enclosing in a tin case, or placing under a weight.

ARTHUR T. COOPER.—The article to which you refer was condensed from the *PHOTOGRAPHIC NEWS*, p. 28, Vol. XIII, January 15, 1869.

J. E.—The general arrangement of your studio, as you describe it, appears good, but the green blinds are undesirable. You will find dark blue better. 2. For convenience of pitch, we should have preferred the ridge a foot or more higher; but we do not see that it need be altered. Almost any colour may be used for a carpet, but we should prefer a mixture of browns, with pattern not too pronounced.

OXONIENSIS.—We cannot, with any certainty, explain the differences in advertisements. Here we must confess ourselves *Davus*, not *Œdipus*. Our conjecture is, that the manufacturer determines a retail price for his article, and allows a certain discount to the dealers, some of whom, anxious to push trade on the principle of quick returns and small profits, offer the article in question (collodion) at a very slight advance upon the price they pay the manufacturer. In some trades a leading article is sold without profit, to attract custom. In other trades—bookselling, for instance—some tradesmen regularly allow a discount off the published price, in order to secure custom. We do not know that the article at the cheap rate is ever any worse in quality than when sold at the full price, but, in our observation, the practice has a tendency, through a series of reactions not necessary to trace here, to the general deterioration of goods.

BELMONT.—There are many modes of reducing the tendency to intensity. We before advised the free use of bromides. If that is insufficient, use a somewhat weaker nitrate bath, or use a strong developer, and flush the plate with a large quantity of it in developing. Or use a newer collodion, or dilute the collodion with a little alcohol and ether. Any, or a combination, of these means tends to reduce the production of intensity in the negative. What proportion of bromide are you now using in your collodion? What strength of bath? And what kind of developer? As a rule, free use of bromide is the safest aid in the matter.

G. P.—Where rinsing the paper after removal from the silver bath is recommended, the sheet is to be immersed, and passed through the water, and then hung up to dry. Where it is recommended to blot it off instead of rinsing, a fresh sheet of blotting-paper is laid upon each sheet of paper until the number is completed; they are then taken out and allowed to dry. The blotting-paper may be used over again two or three times. Distilled water is best; it will not soon become too charged with silver to do injury. After fuming and printing, the prints will not require soaking before toning; but it will be as well to immerse them in water, so as to become wet all over before placing in the toning bath.

H. W. TASKER.—The *YEAR-BOOK* for 1866 is out of print.

PHONO-PHOTO.—You will unquestionably gain by getting rid of some of the sash-bars. Do not, however, put in ground glass, as it obstructs a great deal of light, and is costly. Put in plain glass, and then treat it with one of the various excellent means of imitating ground which we have described from time to time. Starch paste, for instance, answers well; or stippling with varnish and zinc white, as described by Mr. Edwards in our *YEAR-BOOK* for 1870, also answers admirably. 2. The question entirely depends on size of stops and diameter of lenses. You will ascertain best by trying; but we are disposed to think that the cabinet will be most rapid. 3. The card you enclose is not too dark.

STUDENT.—Schlippe's salt is not usually kept by chemists; but it is possible you may get it by ordering of a London photographic chemist. Hopkins and Williams made it when it first came into vogue. About 50 grains to the ounce may be employed. The image must be converted into iodide or chloride of silver before applying the Schlippe's salt.

JOHN TERRAS.—Splitting of the film in drying may be due to a variety of causes. The most frequent is the plate not having been quite clean or quite dry when coated with collodion, or excess of acid in the bath, or under-exposure and prolonged development, or the use of old, partly decomposed collodion. Besides altering any or all these conditions, there is a safe method of preventing when the tendency is noticed. Before drying the negative, pour a little stale beer or very dilute gum-water over the film. This will check the tendency to splitting. 2. You can only obtain the *Philadelphia Photographer* by ordering it yearly, in which case you must pay in advance, and you will then receive it regularly by post. 3. The journal you mention never came into existence. It was announced, but never issued.

H. B.—Old writing paper can only be converted into a pulp by maceration, tearing up, and pounding by machinery, similar to that used in paper making. 2. Rub white wax into the paper negative before the fire, and then iron between two sheets of blotting-paper to make it even.

T. A. D.—The address of the Fine Art Printing Company working Mr. Woodbury's patent is Hereford House, Brompton.

ARITHMETICAL CURIOSITY.—Our readers interested in this question will have noticed that in the communication of "*Arithmos*," on the subject, a misprint occurred, in which 3774 is printed for 3744.

JAS. HALL.—With some samples of paper there is a tendency for the prints to become a little deeper in tone in the fixing bath; but in the majority of cases it is due to a trace of acidity in the fixing bath. If you are quite sure your hypo bath is neutral or slightly alkaline, and the prints well washed after toning, then your only remedy is to remove the prints from the toning bath when they are considerably too warm. If the prints enclosed be an example of the result, it is partly due to another cause. The print, although very good, is from a negative which is just a trace too thin, which does not permit the reduction of much silver in printing. Prints so produced generally run to lilac tint as soon as they are past a drab tint.

S. W. BARNES.—We have no means of ascertaining whether the photograph you enclose is or is not copyright. If it be copyright, you, of course run risk in copying it.

M. DEA.—If you paint, or employ some one else to paint, a picture, and duly register it, you can issue photographs of it which cannot, without infringement of copyright, be copied and sold. But this will not invalidate the right of any one else to paint a picture of the same subject, and then photographing and selling the prints.

"PERSONAL INSTRUCTION FOR PORTRAITISTS."—We have received several communications for "*H. S.*," the writer of the letter on this subject in our last. Our correspondents will see, on a moment's reflection, that we cannot undertake the office of intermediary in such case. We have no time to transact private agencies. The proper means of making known all business communications is through our business columns.

JOHN STONE.—It has been asserted that water in freezing eliminates impurities, and becomes equal to distilled water. We have not personally given the subject much attention, but we doubt the statement.

HENRY VIAL.—India-rubber which has been exposed to light often becomes insoluble in its usual menstruum. Take a piece of india-rubber and cut away the black outside, only using the light-coloured inside portion. You will probably find that dissolve readily if pure. The solution should be filtered. You may use the same chloroform. 2. The solutions will keep separately. You acted wisely in the matter of the still.

J. W. CAMPBELL.—You may communicate with the small sum you mention. Go to a respectable dealer who is also a practical man, and state the facts; he will give you good advice. A tent will serve, but a dark room is better. Try Mr. Hughes's, 379, Oxford Street.

G. N.—The hours of business vary in different houses, and for different departments. Operators usually work from nine in the morning until dark. Printers often commence at eight in summer. We will examine the coloured portraits if you send them to our office.

E. WILLIAMS.—The advertiser in question was Mr. Godbold, of St. Leonards, whom we know to be a respectable man. The neglect must have been an oversight. Your letter got overlooked last week.

R. TUDOR WILLIAMS.—Many thanks. We shall have much pleasure in forwarding the coffee prints. The portraits are very excellent indeed; soft, delicate, forcible, and rich as photographs, they are also satisfactory and artistic in arrangement. They are decidedly above the average quality of portraiture with which we meet. Thanks for the communication. In our next.

F. BOSWELL (Lynce Regis).—We have received three prints without any communication respecting them.

CAPTAIN ROSS THOMPSON.—Thanks. We shall publish the ingenious hint shortly.

The Communications of G. R. Gill, W. Marquand, and Isaac Wilde, are again compelled to stand over until next week.

E. P. OGIER.—Thanks. In our next.

Several Correspondents in our next.

CAMPHOR IN COLLODION.

A PARAGRAPH recently appeared in the *Athenæum*, and has since been quoted in some other journals, describing some experiments with gun-cotton, published by Professor Seely in New York, which, although interesting in a chemical point of view, may mislead photographers unless accompanied by further information. Professor Seely points out that whilst ordinary gun-cotton or pyroxyline is insoluble in alcohol alone, the addition of a little alcohol at once produces solubility. The value of camphor in aiding the solubility of gun-cotton in various menstrua is well known in this country, and has been rendered available in the manufacture of xylonite, as described in our last volume; and the addition of camphor to collodion for photographic purposes was the subject of a patent in this country about sixteen or seventeen years ago.

At the last meeting of the Liverpool Amateur Photographic Association we notice that Mr. Green, calling attention to Professor Seely's experiments, made a suggestion which was excellent in itself, and which, if the premises had not needed qualification, might have been very valuable. He thought that that singular fact, to which the paragraph in question referred, might be of much importance to photographers, as it might enable them to dispense with ether, which, comparatively with alcohol, was a very unstable compound. It might also shorten the exposure, by keeping the film of dry plates in a better condition for the action of the developer. He thought it might also act like oil of cloves, and similar hydrocarbons, in facilitating reduction of silver from its compounds; and, if so, might in that way shorten exposure. Mr. Green's conjecture very accurately represents the actual facts. The action of camphor in collodion is very similar to that of oil of cloves and other bodies facilitating the reduction of silver. A dozen or fifteen years ago we made a tolerably complete series of experiments on the effect of various additions to collodion—camphor, wax, glycerine, glycerine, grape sugar, honey, gallic acid, resins, and various essential oils. It is not necessary to recount all the details of our experience here; it is sufficient to say that the temporary advantages gained by the use of some of these substances was more than compensated by the subsequent losses. With camphor, at the rate of one grain to each ounce of collodion, as used in Cutting's patent process, the advantage gained, either in sensitiveness or vigour, was less palpable than with many other substances, whilst the disadvantages were very definite. The first defect which attracted attention in a negative taken with the camphorated collodion was the complete opacity of the film throughout. Camphor being an opaque gum, the collodion film in which it is present dries white and opaque, giving the appearance of fog to the image.

It is true that after varnishing, this disappears; but it is inconvenient, and deceiving to the eye, to have to deal with a negative presenting this fogged appearance. The bath used with collodion acquired a tendency to fog, and the collodion itself was not stable.

Our object in recalling these experiences is not to discourage experiment. We believe that it is always interesting and instructive to repeat old experiments in the light of fresh knowledge. We simply mention these facts by way of caution to the experimentalist, and to suggest that his operations should be conducted on an experimental scale, that he may not risk the injury or derangement of large quantities of material which may be working well now, but might, by incautious experiment, be rendered useless.

AMERICAN PHOTOGRAPHIC EXHIBITION.

THE next American Photographic Exhibition, held under the auspices of the National Photographic Association, will open in Philadelphia on June 6th. Our American friends are especially anxious to receive contributions from the Old World, and every arrangement will be made to give ample space, and good position and light, to foreign contributions. A grant from Congress allows the entrance and return of foreign specimens free of duty. Photographers who desire that what they send should be sold on their account, and not returned, will receive the best attention to their wishes. In all cases, two itemized invoices should be sent by mail, and notice as to date of shipment, name of steamer, &c. Packages should not be sent later than April 15th; but if sent at any time earlier (and the earlier the better), they will be carefully stored. All packages should be addressed as follows:—National Photographic Exhibition, care Edward L. Wilson, Secretary, Philadelphia, U.S.A.

We hope, in the course of a week or two, to be able to announce that arrangements are made to send all the cases to one person in London, who will pack the cases sent to him in one or more large cases, and undertake the shipment, in which case the National Association will pay the freight to America. For the credit of England, and the perpetuation of the fraternal feeling existing between American and English photographers, we hope that a fine collection of photographs may be sent from this country, and we urge the matter on the attention of our readers.

PHOTOGRAPHY AND THE ECLIPSE.

IN spite of delays, mismanagement, and mishaps, the photographic observations in connection with the English eclipse expedition were not altogether a failure. Our readers are familiar with the delay in the preparations

for the expedition, owing to the tardy response of the Government to the application for aid in carrying out the arrangements; and with the uncertainties of the last moment, when it was discovered, that no funds remained to secure competent aid. Accidents and shipwreck *en route* followed; and unfavourable weather at the critical moment, at more than one of the stations of observation, threatened to render the best arranged plans of little avail. Notwithstanding this, Lord Lindsay, at Cadiz, obtained nine photographs, and Mr. Fryer and Mr. Brothers, at Syracuse, obtained six photographs. A few days previous to the starting of the expedition we received a telegram from Mr. Brothers, asking for the address of Dr. Vogel, as it had been resolved on, at the last moment, to secure his valuable aid, and he was, we believe, the only scientific man who had had photographic experience on a similar occasion who was present. As our readers know, he joined Mr. Lockyer's expedition *en route*, and they have already read his graphic narrative of the observations at Mount Etua. We now subjoin some particulars furnished by Mr. Brothers to the *English Mechanic*. After some preliminary remarks, he says:—

The temperature at Syracuse on the day of the eclipse at twelve o'clock, in the shade, was 60·5° Fah.; but, during the same week, 70° in the shade was registered. At night, the lowest temperature was 46°. I have no record of the temperature during the totality, but it was decidedly "chilly."

The weather for some days previous to the 22nd was very fine, and particularly favourable for photographic work, but the barometer had shown a tendency to fall. We also observed that Etna, which was about forty miles distant, and which had been remarkably distinct, became clouded.

The morning of the 22nd was somewhat cloudy, but the sky cleared, and the sun remained bright until within about an hour of totality, when a dense cloud came up, and we had almost abandoned all hope of seeing any other eclipse than the one caused by the cloud. Darkness continued to increase, and we saw the sun no more until within a few minutes of the disappearance of the last gleam of sunlight, when the thin crescent of the sun made its appearance through an opening in the cloud, which we could now see was thinning off, and there was a prospect, after all, of our getting some photographs. The sky, in every other part excepting near the horizon and just in the neighbourhood of the sun, was brilliantly clear.

For about fifteen minutes before totality I had been occupied in the dark room preparing six plates; but when I came into the observatory, about two minutes before the time, I was much struck by the beauty of the sight which at once attracted my attention. The darkness of the eclipse was fast approaching, but there was distinctly seen through the cloud the crescent sun, giving just sufficient light to illuminate the fleecy cloud bordering the denser parts, and producing a very beautiful effect—brilliant rainbow tints being reflected, not in broad masses of colour, as we see in a rainbow, but broken up, and producing more of the effect of sunlight reflected from drops of dew than anything else with which I can compare it.

The critical moment was fast approaching. At last Mr. Fryer, who had been watching through a small telescope for the disappearance of the last ray of sunlight, gave the signal "total," and our work commenced.

I must pause here to say something of the preparation we had made before leaving England and after our arrival at Syracuse. I will first state what we proposed to do, and then describe how we did it.

Photography was, I believe, first employed by Dr. De la Rue and Father Secchi, in Spain, in the year 1860, when the red prominences were successfully photographed, and at the same time proved to belong to the sun. Again, in India and America the red flames obtained the chief share of attention, but observation had been scarcely at all directed to the corona. Faint traces, however, of this mysterious light were found on the photographic plates. The corona had, indeed, been known as one of the phenomena of all total eclipses of the sun, but very little attention had been paid to it while the prominences attracted so much notice. It was, however, determined by the English observers, that during the recent eclipse, the corona almost exclusively should be observed, and I was requested to take charge of the photographic arrangements. Bearing in mind all that had been done during previous eclipses, it

appeared that the corona could not be successfully photographed if a telescope were used for the purpose. There are objections to both reflectors and refractors. I therefore determined to attack the matter somewhat differently, and, as the event proved, successfully.

The corona has usually shown itself on the photographic plate merely as a bright light extending a very short distance from the moon's limb; but all observers of the phenomena speak of this bright light as extending much further, and of rays projecting in some cases one or two diameters in every direction around the moon, and presenting all sorts of fantastic shapes. These appearances also have been said by some observers to change during the eclipse. The small extent of the corona hitherto photographed had given rise to the idea that its light was not very actinic, and that a very long exposure would be necessary to photograph the image. That I might obtain negatives showing the rays and a corona such as is usually visible to the naked eye, and also test the matter as to the actinism of the light, I determined to take several pictures, and to give each plate a different exposure.

It is, perhaps, unnecessary here to describe the telescope, cameras, and observatory. I will merely say that the telescope was one belonging to the Royal Astronomical Society; that the framework of the observatory and dark room was constructed in England, and was forwarded by way of Malta (with the other heavy baggage), so as to be ready immediately on our arrival at Syracuse, thus saving time, few hours sufficing to put the erection together. The whole was covered with thin waterproof canvas, and as an additional protection, chiefly from the wind, a large sail was securely fastened over the building—a protection of the value of which we had ample proof before our work was over.

To the eyepiece end of the telescope (which is mounted on the German plan, and driven by clockwork) was fixed the camera for taking photographs of the partial phases, and also for taking one picture during the totality. Mounted on the telescope was the camera for photographing the corona. I wished to obtain the pictures with short exposures, and yet to get as large an image as possible. Fortunately, an instrument combining these two qualities—a long focus and quick-acting—was available, Mr. Dallmeyer having very kindly lent me one of his "rapid rectilinear" lenses of 4in. aperture and 30in. focus, giving an image of the sun 3·10in. in diameter. This lens was fixed to a camera adapted for plates 5in. square. Six dark slides were prepared and fitted for use in either camera. As I had to do the whole of the photographic manipulation myself, a large number of partial phase pictures could not be taken—time was lost in the preparation and development of the plates—but I secured about nine negatives before clouds prevented further work. My plan was to prepare three plates, and expose them after intervals of two minutes; then develop, and so on up to the time when it was necessary to get ready for the totality.

I had found that it required two minutes to prepare each plate, and at fifteen minutes before totality I commenced the preparation of the six plates required. No. 1 was placed ready in the camera for the corona, and No. 6 was put into the telescope camera ready for exposure at the proper time. We had arranged a scale of exposures varying from three to thirty seconds, and we had found, by repeated drilling, that it required about six seconds to change the slides and make the exposures. We had previously decided that we would go through the ceremony of exposing the plates regardless of the atmospheric conditions at the time, and so take the chance of any break in the cloud which might occur. Exposure No. 1 was, therefore, made with very little prospect of success, and it came out blank, No. 2 and the others following in their proper order; the whole showing results, but No. 5 giving a perfect picture. The cloud had completely cleared away by the time this picture was taken. No. 6 was exposed three seconds in the telescope for the prominences.

The plate No. 5 was exposed eight seconds. It is, of course, impossible to say whether this plate shows as much of the corona as would have been seen on the plate exposed thirty seconds if there had been no cloud at the time when that picture was taken; but, as it shows the corona extending about a degree on the north and west sides of the moon, and less on the east and south, and as one of the observers who was watching through a telescope for the re-appearance of the sun assures me that there was no cloud at the time my photograph was taken, it is, I think, safe to assume that the whole of the corona is shown on this plate.

How could six photographs be taken in 105 seconds? This is a question which will, no doubt, occur to many readers. It was done in the manner following:—Mr. Fryer stood at the end of the telescope ready to uncover the camera at the appointed time. Lieutenant Spaight (who had very kindly consented to assist us) was standing near my right hand ready to give me the dark slides, and to take those already exposed from me, and Sapper W. Gardiner was at the chronometer counting seconds, and I was stationed at the telescope. The changing of the slides was effected in six seconds each, and at the finish we had about two or three seconds to spare.

It might be asked why we did not use repeating frames. This was thought of, but decided against, for reasons which I need not particularize here. I believe the plan adopted was the best.

Immediately after the end of totality I commenced the development of the plates, and most anxiously did I watch for the appearance of the image. My anxiety was not of long duration; the picture was there, and good beyond all expectation; this was plate 5. The other plates were all under-exposed, as I have before stated, owing to the partial cloud.

Early in the day a strong breeze sprang up, and at the time of the eclipse it was blowing half a gale; consequently clouds of dust covered everything. This we attempted to keep down by watering, but only with partial success; and, worse than all, the cloud, no larger than could be covered with the hand when held with the arm extended, and yet which appeared not to move, threatened total failure. Fortunately, we were deceived in this respect; the cloud did move, and we obtained at least one good picture of the corona. The effect of the wind can be seen in most of the pictures by the traces which the red prominences have made. Red is not usually considered to be very active in its effects on the photographic plate; but these strange appendages of the sun form an exception to the rule. The light from them is extremely quick in its action—many times more so than the light of the corona, which has more of the character of moonlight in its photographic action. The gusts of wind appear to have caught the telescope, and the images of the prominences have left their marks where the dark outline of the moon should be; and then the telescope has gone back to its place again. The effect of this has been, no doubt, to soften the corona; but the coronal light being so much less actinic, the vibrations of the telescope have not materially affected the *form* or *extent* of the corona. The disc of the moon should, of course, appear perfectly circular, but the light has *eaten into* the moon's limb. This might have happened to some extent, probably, if there had been no wind, owing to the tendency of the silver to form a greater deposit on those parts where the action of the light has been greatest; but the doubling of the image has been the chief cause of the irregular shape. The north and south limbs of the moon are perfectly sharp *where there are no prominences*; and I consider this a proof that the detail of the corona has not been injured by the doubling of the image in other respects.

The readers of this article who are interested in photography will no doubt say: "What process do you use? What collodion? What developer?" &c. To all I reply, that I used a process for obtaining negatives; that any process which will work quickly, and give clean pictures, would have answered the purpose. In fact, just the process that any one would employ who wished to take good landscapes. Were I again to attempt to photograph an eclipse of the sun, I should perhaps adopt a different plan. What we want is a picture of the phenomenon such as we see with the naked eye; and for that purpose the old, and now almost disused, positive process on glass—the process by which those exquisite pictures one now so seldom sees were produced—is the one I should prefer to use. This would give a picture from which negatives could be made of any size, and, for certain details, could still be viewed by transmitted light.

PARCHMENT PAPER AND HYDRATE OF CHLORAL.

BY T. L. Phipson, Ph.D., F.C.S.

THE modified form of cellulose known as parchment paper, obtained by passing sheets of paper through sulphuric acid diluted with half its volume of water, and remarkable for its toughness compared to ordinary paper, becomes

extremely brittle when submitted for a certain time to the vapour of chloral hydrate of the ordinary temperature of the air, or when left in contact with this substance, and can then be easily rubbed to a powder.

A SIMPLE DRYING BOX.

BY E. TUDOR WILLIAMS.

THE following will be found a cheap and easy way of making a very efficient drying box for dry-plate work, viz:—

Procure two old tea chests, the one slightly larger than the other, so that the larger may be made into a lid in such a way that it drops over the smaller or box part, similar to the way in which the lid fits on a pill-box, but care must be taken that it does *not* fit too tight. Both box and lid must be lined with thick brown paper, to exclude all white light. The box is then complete.

For resting the plates and avoiding any contamination, it is necessary that tumbler glass or marmalade jars should be arranged round the inside, one for each plate to be dried, also a dish to contain the sulphuric acid that acts as the drying medium.

I have a box so made that has been in use over twelve months, and see no reason to abandon it for any other or more expensive form; indeed, coffee plates dried in this kind of box, by the means of sulphuric acid, I have kept for eight months before exposure without the slightest perceptible deterioration.

MY EXPERIENCE WITH WASHED PAPER PRINTING.

BY B. WYLES.

THERE seems to be a good deal of difference of opinion on the advantage of washing paper for commercial printing. Will you allow me to record my vote decidedly in its favour? Yet I can quite appreciate the difficulties which some have found in working it.

Our usual printing had been with a 40-grain silver bath, to which nitrate of soda was added, and the sheets were blotted off between white blotting paper. Now, when the sheets were washed in three or four waters, then blotted off as usual, and printed with fumed pads, the prints dried a peculiar nasty bluish-black, quite different to our usual tone; and no difference was made by taking them out of the toning bath earlier; no matter how agreeable the tone whilst wet, they went to the blue dirty black on drying.

This peculiar appearance has been attributed as a necessary result of the washed paper process. It can scarcely be so, as we have got rid of it entirely, and now get any tone required, just as used to be the case before washing, with the addition of some advantages which the old plan had not.

The procedure was as follows:—The previously slightly acid nitrate bath had a few drops of liquid ammonia put to it, the paper was rinsed through one water, instead of three or four, and the blotting papers were discarded; the paper being hung up till surface dry, and then finished off by the fire.

To conclude, with the exception of the whites being purer, and so giving the prints a more vigorous appearance, no one could tell from the tones that the paper had been washed and fumed. But in working there is much greater latitude in keeping the paper good, and a greater number can be got off in a given time, on account of its quick printing. I, therefore, consider it, from a commercial point of view, not merely practicable, but of great advantage. I am the more glad to be able to say this, as at first the colour of the prints threatened to force us back to the old system. Now, I think, the failures are fewer than with the ordinary mode of printing.

SUGGESTION FOR AN ACTINOMETER.

BY W. MARQUAND.

THE diagram illustrates an idea of an actinometer for showing the variations of the light's activity during the day. A strip of sensitive paper is made to travel from A towards B by means of clockwork at a fixed speed, say half an hour for a given portion to do the whole distance.

When the paper arrives at B, it will have darkened more or less, according to the light's activity, and correspond with one of the painted tints. If the light should be so powerful as to make the paper darker than No. 6, the shield A must be slipped towards B, thus reducing the length of the opening, and the extent of the reduction read off on the edge thereof.

Guernsey.

KEEPING THE NEGATIVE BATH IN WORKING ORDER.

BY ELBERT ANDERSON.

MR. ANDERSON, in our Philadelphia contemporary, still continues his dialogue instructions. In the following conversation he reviews some of the diverse opinions on the treatment of the nitrate bath, and gives his own method to his pupil, Mr. Marshall. Mr. Anderson commences:—

I have told you that a bath of three gallons will sensitize upwards of 600 4-4 plates, and may require filtering once—twice at most. Somewhat depends upon your own cleanliness of manipulation. A half-gallon bath, newly made, may very properly be iodized by coating a 4-4 plate twice with collodion, and leaving it in the solution over night.

M. I met a feller out west, who told me that he found his bath worked better the older it got; and, in fact, that he got better chemical effects as his bath approached over-iodizing. Is there anything in this?

A. The "feller out west" certainly knew what he was talking about. Unquestionably, as the bath approaches a state of saturation with iodide, the best chemical effects are procured, from the simple fact that the iodized film is less and less interfered with, the saturation of the solution preventing its attacking the film. That fact alone is one in a dozen good reasons for using a large bath, well iodized, as you may thus use it for a long time without its becoming over-iodized. E. L. Wilson says:—"A bath not saturated with iodide of silver will produce unequal results." He makes no allusion here to those little "tuppeny" baths of half a gallon, which must go out of order every semi-occasionally, for which reason you cannot iodize sufficiently without overdoing it after dipping very few plates.

M. "Devine's Practice" says:—"Every plate must be removed from the bath as soon as coated, that the solution may be preserved as long as possible below the point of saturation." It strikes me that this gentleman's head is level.

A. You are right; and "Lea's Manual" answers it completely: "The plate should never be left in the bath longer than necessary."

M. Now here's something that is an enigma to me, which might even bother the Sphynx herself. I will read it to you, from "Hardwich's Chemistry," 7th edition, p. 521:—"When the iodide of silver, previously dissolved in the bath, crystallizes upon the film, leave a plate in the solution all night, that the excess of iodide of silver may gradually crystallize upon its

surface, and so be removed." Now, considering that you have taught me that this dipping of plates in the bath was the very cause of its becoming over-iodized, and now I am told, on the contrary, that this is the method of removing it, I am rather muddled.

A. I cannot conceive how Mr. Hardwich could have written this paragraph as it now reads. Either I don't understand what he means at all, or else "Why, this is lunatics; this is mad as a mad dog!"

M. Now we come to sunning the bath. What do you say—sun or not sun?

A. If the bath be put in the sun whilst it (the bath, you know, not the sun) is acid, it might be left there a year without the sun's having the least effect upon it. It must be first made slightly alkaline, when the effect of the sun's rays will be to blacken the solution from organic matter, which will finally be thrown down as a black powder, and when the solution becomes perfectly clear, all further action ceases.

M. It does benefit the bath, then?

A. Yes, of course.

M. You say, "Yes, of course," but you hold something in reservation, I know.

A. I do. Boiling a bath properly for an hour will do more good than sunning it for a year. I never sun a bath.

M. "It has, however, been justly remarked that, in diluting the bath, the disordered bath must be poured into the water, and not the reverse." (M. C. Lea, *Mosaics*, 1867, page 10.) Then follows the word, "WHY?"

A. Mr. Lea is correct; and when we come to renovate our bath, you will be told "WHY?"

M. Another passage says: "When, in the course of time, the bath becomes saturated with iodide of silver, add crystals of nitrate of silver." But Devine enters a protest.

A. I agree thoroughly with Devine, "and" (to quote his words) "advise the operator never to strengthen his bath until it is thoroughly renovated and made over." And now, Mr. Marshall, what do you think of the following?—"Better make a new bath than repair the old one, since nothing satisfactory will be likely to be got from it." (R. D. Ewing, *Mosaics*, 1870, page 54.) Considering that I have been "repairing" my bath for about four years past, and have received the first premiums at all the Fairs of the American Institute during this period, I am not unnaturally led to suppose that something "satisfactory" has been got from it.

M. Well, yes; "it does look that way," certainly. But you must have made a new bath some time or other, or else you must have a "healthy old bath" by this time.

A. There stands in Milan an old cathedral, where visitors are shown a wheelbarrow supposed to have been blessed by some patron saint hundreds and hundreds of years ago, and yet it has been used ever since to perform the roughest kind of work, and is at this present day just as good, aye, better than now; in fact, it never will wear out.

M. Never is a long day. Why won't it wear out?

A. Because, in former years, when it was first put in use, the wheel broke, and so they got a new one put in; later the bottom fell out, and a new one was put in, in its place; by and bye, the handles broke, one after another, these in turn were replaced by new ones; next the new wheel gave out, and was replaced; again the bottom succumbed, and so this has been going on for hundreds of years.

M. Yet this is the same wheelbarrow (!)

A. Exactly. Like my bath, it's the same one; repaired from time to time, ever since it was first made.

M. I should say you were not very partial to new baths.

A. I look upon a new bath pretty much as my cook regards the griddle "buckwheat-cake mornings;" she says she must "grease up and fry two or three rounds" before she can "git things runnin' smooth-like."

M. How do you replenish your bath, then?

A. I have told you I use two baths of about four gallons each. I coat from fifty to sixty 4-4 plates daily, and find they last me about six or eight weeks, during which time I may have filtered once or twice; thus I am enabled to coat upwards of two thousand plates before any signs of exhaustion exhibit themselves. In the meantime, I make up a bath two gallons at twenty grains strong, and, in an alkaline state, boil down to forty grains. Iodize as before stated, by leaving in an eight by ten plate all night. I use this as opportunities present themselves, and in a short time it works perfectly. I then decant this into a large demijohn, and, if necessary, make

another, or more, and it is with these I replenish the larger baths.

M. What is the best method of abstracting water from collodion?

A. I should suggest, as the best method of doing this, "chucking" the collodion out of the window.

M. Now a question of developing. How is your developer made?

A. I make two solutions as follows: No. 1. 1 ounce proto-sulphate of iron, 1 ounce of acetic acid "No. 8," and 12 ounces of water. No. 2. 1 ounce iron, 2 ounces acid, 23 ounces water; alcohol (only if necessary) enough to make it flow over your plate smoothly. Mix proportions of Nos. 1 and 2 to suit. Much depends upon light, exposure, drapery, weather, &c. In case of children, where you cannot get "time," use No. 1. With a fine light and full time, use No. 2; even weaker. I have never noticed the effects alluded to on these last-mentioned.

M. C. W. Hull says: "In developing, hold the plate absolutely still; by so doing the detail is better obtained." How is that?

A. Assuredly. I have seen some operators (!) "jiggle" a plate up and down as if they were trying to balance a marble on its surface. Why, I cannot conceive; that's probably one of the "secrets of the dark chamber."

M. E. Dunmore says: "Use the developer with a lavish hand; never mind the silver washing off." Is this "sound on the goose?"

A. I flow my plate as rapidly as possible, and endeavour to wash off all the silver I can. There is always plenty left, and to spare. And, I make my developer fresh every day.

M. "Devine's Practice" says: "The operator should aim to get his negative intense enough after one development with iron; there will generally be found no difficulty in accomplishing this object."

A. I find no difficulty whatever. Beware of strengthening (!) Remember what Crockett says: "Be sure you are right, and then go ahead."

M. What is the effect of bromide in reducing contrast?

A. If the contrast is caused by improper lighting, don't look to your chemicals to remedy it. A proportion of about three of bromide to five of iodide is not far out of the way.

PHOTO-MICROGRAPHY.

BY THOMAS HIGGIN.*

THE application of photography to the delineation of microscopic objects dates from the earliest days of photography. It was one of the first uses to which it was applied, and an endeavour was made so far back as twenty-five years ago to give microscopical information in this truthful way at a small cost. The plates then used, silver ones, soon wore out, and it does not appear that any similar attempt has since been made.

The difficulties met with in producing photo-micrographs have caused numbers of persons who have from time to time taken the matter up to abandon the study, and the hopelessness of finding a sale amongst the general public has prevented professional photographers from devoting any time to it. Thus the production of photo-micrographs in this country was mainly confined to a few scientific gentlemen who produced them for their own purposes, until Dr. R. L. Maddox, of Southampton, a few years ago issued his beautiful series for the magic lantern.

It was in the year 1839 that M. Daguerre communicated to the public his discoveries in photography. In the following year Mr. Dancer, of Manchester, produced images of microscopic objects upon silvered plates. In the same year Dr. Donne, of Paris, presented to the Academy of Sciences copies of various microscopic objects on Daguerreotype plates; and five years afterwards he and M. Leon Foucault published an atlas of microscopic anatomy, in which the engravings were printed from Daguerreotype plates which had been chemically etched.

The first publication in this country of photographs of

microscopic specimens took place in the year 1852, when Mr. Joseph Delves presented to the Royal Microscopical Society of London a paper illustrated by beautiful prints from his own collodion negatives, and this paper, with its illustrations, appeared in the next issue of the *Journal of Microscopical Science*.

The art has been fortunate enough to obtain Government patronage in the United States, and it is in Washington that the greatest advances have been made, and where it has been availed of for recording microscopical information on a large scale. The Army Medical Museum there is rich in the productions of Dr. J. J. Woodward and Dr. Curtis; and the researches of these gentlemen appear from time to time in reports issued by the War Department. Dr. Woodward has introduced the use of the heliostat, and has designed one for photographic purposes. By the application of this instrument the greatest difficulty in manipulation has been overcome. He has also introduced an amplifier, a double concave lens, used in the place of the eyepiece, by means of which, with the one-eighth, an object may be magnified as many times as by the one-fiftieth alone, and with quite as good definition. This amplifier is made by Mr. Wales, of Jersey City, New York, at a cost of about 30s.

The use of the cell containing a solution of ammonio-sulphate of copper is also due to Dr. Woodward. This solution stops the heat rays in their passage from the mirror, but does not interfere with the actinic rays. Dr. Vogel has stated lately that this solution serves to render the chemical and visual foci coincident. I am not able to say whether this is so or not.

The most ardent worker in this country has been Dr. Maddox. He has perseveringly stuck to his love, has overcome the various difficulties which stopped other men, and has always been ready to communicate for the benefit of others the results of his labours. He has photographed a variety of objects, not excepting living objects. In 1867 he illustrated a paper read before the Royal Society with photographs made from an *Aquatic Larva* whilst living. Most of the photo-micrographs hitherto produced have been made by means of transmitted light; some have been produced by reflected light, but these have not generally been successful or satisfactory. The powers generally used for the table microscope are employed, but if the visual and actinic foci are not coincident, they require to be corrected in order to work with any degree of comfort.

Before the heliostat was used there existed very great difficulty in using the higher powers. The illumination might be made satisfactorily, but, before the plate could be got ready, the altered position of the sun made it necessary to readjust the mirror; and this had to be done over and over again so often that patience became exhausted, and the pursuit was abandoned. But with the heliostat the light, once adjusted, requires little consideration. The mirror of the heliostat follows the sun, and throws the light on the mirror of the microscope in exactly the same position for hours together.

Dr. Woodward thus describes the heliostat designed by him:—"It is designed to throw a steady beam of sunlight in the direction of the south pole of the heavens. It consists essentially of a mirror adjustable perpendicularly according to the declination of the sun, and attached to the south end of a rod set parallel to the axis of the earth. This rod is then rotated at the rate of one revolution in twenty-four hours, by having a wheel fixed upon it which is connected by a band with the arbor of the hour-hand of an ordinary clock." The one on the table was made for me by Messrs. Abraham and Co., of Liverpool, from a drawing sent to me by Dr. Woodward.

Sunlight is the source of illumination generally employed, because it costs nothing, and gives the best definition; but when it is not possible or convenient to use sunlight, the electric light, the oxyhydrogen light, or the magnesium light, may be used.

Having got a good source of illumination requiring little

* Read at a meeting of the Liverpool Amateur Photographic Association, February 23, 1871.

further attention, the next difficulties met with arise from the impossibility of being at both ends of the camera at the same time; some mechanical arrangement becomes necessary to enable the operator to manipulate the microscope whilst arranging the image on the screen of the camera. Dr. Woodward has got over this difficulty by converting his operating-room into a camera, and lately Dr. Maddox has followed his example. The adoption of this plan enables them to sit down before the microscope and use it as they would for ordinary purposes, and, when all is adjusted, the removal of the eyepiece allows the image to fall on the screen. The final adjustment of the focus can only be done at the screen of the camera, and some arrangement is necessary by which the fine adjustment of the microscope can be communicated with whilst viewing the image on the screen with a focussing-glass.

The disadvantage of Dr. Woodward's arrangement appears to be—that part of his apparatus (the heliostat and mirror) is outside his window, it being necessary to adjust the mirror by means of rods passing through the shutter. In addition to this, it is not always convenient to convert a room into a camera.

In the arrangement I have adopted, I have the heliostat upon the camera, and whilst standing towards the front of the camera it is within easy reach, as is also the mirror, the condenser, the stage, and the coarser adjustment; and a small opening in front enables me to see the image upon a sheet of opal glass, which is placed in the dark back—in the place afterwards to be occupied by the sensitized plate. The interior arrangements of the camera may be thus described:—The carrier for the objective is attached to a plate of zinc, which is moved by the fine adjustment rod worked from the screen end of the camera; this plate travels upon another plate moved by a rack worked by the milled heads at the sides of the camera. The camera stands in a window having a southern aspect, and I do not find it necessary to have the window open whilst operating.

Dr. Woodward focusses upon a sheet of plain plate glass. I do not experience any difficulty in focussing upon a sheet of ground glass. I use, for a focussing-glass, a hand-microscope, with a two-inch objective set for the ground surface of the glass.

Dr. Woodward has been successful in using all the powers of the microscope up to the one-fiftieth; but he tells us that the pathological photographs executed under his direction have been chiefly taken by means of low powers, the objects being magnified from twelve to fifty diameters—in other words, with objectives ranging from the two-inch to two-thirds.

My own experience proves that the low powers are those most generally useful; and this is important, because it is easier to work with them, and they are less costly. I find a four-inch objective makes an excellent condenser for all these powers, but, when higher powers are employed, it is necessary to use an achromatic condenser of the best description.

The manipulation having been so much simplified, and the great difficulties overcome, it is to be hoped that a much larger number of persons will be induced to take up this most interesting and engaging work; and there is really no reason why anyone possessing a good microscope should not, if so inclined, use it for the production of photo-micrographs. A very small amount of knowledge of photographic manipulation and chemistry is sufficient; and at the present time, when collodio-bromide plates can be purchased ready for exposure, and which will keep sensitive almost any length of time, the art is open to a vast number of persons—in fact, to any one who possesses a microscope.

Speaking of the collodio-bromide process, I cannot help remarking that it is becoming the dry process of the day. I regret, however, to see that, as in the case of astro-photography, which received its first great impulse in Liverpool, when the splendid photographs of the moon were produced by Liverpool amateurs, and exhibited to the members of

the British Association in St. George's Hall in the year 1854, Liverpool amateurs are allowing others to appropriate the honour due to them. The advertisements in the journals read as if this process was the discovery of Mr. M. Carey Lea and Mr. Dawson, although the discovery is entirely due to Liverpool amateurs, Mr. Sayce and Mr. Bolton, and the process was perfected and in general use by the members of this Association before these gentlemen ever worked it at all, and I understand that the original formula has never been improved upon.

Dr. Woodward tells us that his form of heliostat can be produced in the United States for ten dollars; and a simple camera with the baseboard extended in front, to carry the microscope laid in a horizontal position, with a rod running through it carrying a wheel to communicate with the fine adjustment by means of an elastic band, need cost very little, and gives everything necessary. For a full description, with drawing, of what appears to me to be the simplest arrangement capable of producing good results, I beg to refer to *The British Journal Photographic Almanac*, pages 38 to 40.

The application of photography to art and science is beginning to occupy a good deal of attention. Papers are being read before various scientific associations, and some of our monthly publications contain articles on the subject. The photographic exhibitions contain specimens of the different ways in which it is being successfully and advantageously employed. The instructors in our large educational establishments are beginning to feel that the value of their lectures would be much enhanced, and much valuable time saved, if microscopical information could be supplied in a cheap form in a way to be seen by large numbers at a time. The attention of Mr. Henry Cole, of the South Kensington Museum, has lately been directed to this subject, and the large photograph of the larva of one of the tortoise beetles has been produced at the South Kensington Museum within the last few weeks under his directions from one of my negatives. Such photographs must prove very useful for class instruction where it is not convenient to use microscopes, and, when doing so, would consume too much time. The lecturer would, by these means, find the task of describing his subject much facilitated.

Photo-micrography may also become very useful for the purposes of original scientific research, and when its use becomes more general, and records are taken in this way of what has been seen, many differences of opinion and disputes which have previously arisen will exist no more.

Amongst other ways in which photo-micrography may become useful, it has been suggested by my friend, the Rev. H. H. Higgins, that photography might be advantageously employed in delineating the microscopical view of various articles of commerce, thus demonstrating the causes which render some descriptions more valuable than others, and, whilst no verbal descriptions would be likely to lead to the employment of the microscope more generally in the examination of various samples of produce, the production of photo-micrographs might initiate changes in buying and selling of which it is impossible to see the full results. In the article of starch, now largely used in the manufacturing districts, the publication of drawings of the forms of the various starch grains has led to the constant and daily use of the microscope for the examination of the different samples offered for sale, and it is the only way in which the various adulterations can be detected, and by which it may be known with certainty what samples are suited to the purposes of the manufacturers, and what are not. I allude particularly to the use of starch in preparing mordants for the calico printers.

In the same way photo-micrographic delineations would be likely to lead to the use of the microscope in the examination of samples of flour, thus detecting at once the presence of unsoundness, whereas at the present time every

sample of flour has to be tested by being made into bread. There could surely be no difficulty in detecting flour made from sprouted wheat, or detecting the admixture of flour of this kind with that made from sound wheat. Similarly, it may lead to the examination of various samples of cotton, some of which cannot now be accurately valued by touch and ordinary sight only.

It appears to me that it is of great importance that "microscopical information thus made permanently accessible to every observer" should be offered to the public at the smallest possible cost. So long as photographs are offered this cannot well be done, the cost of production being too great; but by means of the Woodburytype, or some similar process by which the impression can be transferred to metal plates and large numbers of copies struck off in printing ink, it will be possible to accomplish this. By this process all the delicacy of detail is preserved and reproduced.

The photo-micrographs which I exhibit this evening are large enough probably for all purposes excepting the illustration of lectures, but they cannot be issued at a small price. Professional photographers could not afford to sell them at less than two shillings, but if reproduced by the Woodburytype process I think it likely that they could be sold for sixpence each.

My own efforts in photo-micrography commenced some seventeen years ago, and the negatives which I exhibit to-night were taken by me in the year 1854 by means of a small camera for working plates $6\frac{1}{2}$ by $5\frac{1}{2}$. They were produced in the evening by artificial light, the camera and other apparatus being placed on my dining table. They will serve to show the advances made since that time.

I cannot conclude without alluding to the use which has been made of photography during the Franco-German war. The way in which it has been used is so familiar to us all that I need not do more than allude to it. For months the inhabitants were dependent on micro-photographs carried by pigeons for communication with the outer world, and were it not for them very few persons could have communicated in any way during the siege with their friends shut up in the beleaguered city.

In the years before us perhaps there may not be any startling photographic discoveries, but I am sure of this, that there will be steady advance and improvement in all known processes and appliances, and that every year the application of photography to the purposes of education, and to the spread of scientific knowledge, will be more general and extended, and that each year we shall find it more and more associated with art and science in all their branches. As Liverpool amateurs have hitherto taken a good stand in the foremost rank, so we may expect to see Liverpool names associated with the discoveries and applications of the future; and I take this opportunity of urging the younger members of our Society to emulate those who have preceded them.

PHOTOGRAPHY AND THE ARMY.*

MILITARY organization should be in the nature of an elephant's trunk, which is equally available for raising luggage and picking up pins. Among the pins, with all deference to those practising it, we may rank photography in its relation to war purposes, the value of which has been promptly recognized in the Prussian army. The geographical knowledge possessed by the Prussians—not only as regards their own country, but that of the countries they have invaded—has been matter of wonder. It is, however, easily accounted for. The little hand-map familiar to all travellers in Germany has sufficed for local purposes, while photography has lent its aid in what pertained to foreign countries. It is known that before the campaign in Austria, and again before active proceedings were taken in France, Prussian officers settled down as photographers in towns

and villages importantly situated, in places about which topographical knowledge was likely to be wanted, pursuing their business as if for a living; and, while ostensibly devoting themselves to taking local views, they secured all the necessary topographical and strategical features of the country, and then disappeared. When next seen in those localities it was in uniform, at the head of their men. Now we do not say that this somewhat sneaking style of procedure is to be commended to English officers for imitation; but undoubtedly photography is too valuable an art in its possible relations to military proceedings to be wisely ignored. Its topographical value is not all. The importance of presenting to the eye what is with difficulty conveyed by any verbal description is obvious; while the system of microscopic reduction is simply invaluable as affording a means of rapid and secret communication. What, then, we may fairly ask, are those at the head of our military affairs doing in this matter? The answer is, "As little as possible," and that answer will hardly occasion much astonishment. There is a department of military photography at Chatham, and the art is practised with more or less method at Woolwich. We have heard something also of photography in connection with the Abyssinian expedition, but there has not yet been a full recognition of the advantages offered by it as by telegraphy, and certainly no approach has been made to any organization by which it may be fully utilized, and its available resources adequately and systematically developed. It may appear to some that this is a question of minor importance. Our answer is, that nothing is unimportant which places us at a disadvantage relatively to powerful and aggressive neighbours; while, from a military point of view, importance attaches itself to minutiae. The horse that was lost through the loss of the nail from the horseshoe amply typifies what may be the fate of an army—which often means the fate of a nation—from inattention to trifles.

MANIPULATION.

BY DAVID DUNCAN.*

THE various effects which can be produced in making photographic pictures by a difference in the mode of manipulation is a subject deserving attention—the more deserving because it has hitherto received too little notice, even by those who are termed "skilled manipulators." Photographers, as a rule, bow before the "mighty god Brains," an idol which certainly should command our adoration, but which is robbed of its potency without manipulation. The word manipulation is expressive; there is magic in the sound. To skilfulness therein civilization and the world at large owe much. The cunning and skill of the mechanic, artist, sculptor, or musician depend much on manipulation. So does many a good photograph, though light, temperature, chemical condition, &c., are valuable auxiliaries. That success in the photographer's art owes much to skilful manipulation is a point generally known—a "corn" universally acknowledged. "If you think photography is a mere mechanical business, and success more dependent upon good luck than careful manipulation, get out of it—you are in the wrong business," says Edward L. Wilson in *Mosaics*, 1869. Operators who rarely stoop to notice the cleaning and albuminizing of plates, will find it advantageous to recede a step or two, and become efficient plate preparers. It will be found better than cursing the boy when plates are dirty, or consigning the "nigger" to the nethermost hell. There is more in plate-cleaning and preparing than is dreamt of in our philosophy.

Again, not every one that saith "I am an operator" knoweth how to coat a plate with collodion—a simple matter, apparently, but requiring much skill in the manipulation thereof. No definite mode as to how a plate should be coated can be clearly stated; the operation requires

* *Morning Advertiser.*

* *Philadelphia Photographer.*

judgment, experience, and depends much on the condition or quality of the collodion itself.

It is not my idea, however, to write about skillfulness or unskillfulness in manipulation; the effects of the latter or former are well known. I merely desire to direct attention to the different effects which can be produced at will by altering the method of manipulation. For example, in coating a plate with collodion, one can obtain softness or intensity, fulness of detail or a lack of it, with a good sample, by the *modus operandi*. It is this power that enables one man to obtain pictures of a class widely differing from another, albeit both may never change the mode of working they acquired in the early days of apprenticeship. It is this power which makes a photographer a success or a failure. Further, how various are the effects which can be obtained in a negative by changing the style of development. Flooding the plate, driving the "frec nitrate" before it, and letting the solution run over the sides, yields a negative of one class; pouring on smartly just enough to cover the plate without spilling a drop gives a negative of another. Do not let me be understood to say that because a man lets the solution run over the sides of the plate he is a careless manipulator, for much is dependent on the mode of manipulation, upon the kind of negative he strives to make, or condition of the chemicals.

Only observe the *power* we photographers possess! To make at will—premiing light, temperature, &c., aid us—by experience and practice, a "hard" negative or "soft" one, a "thick" one or a "thin" one. Further still; the fine details of a picture can be arrested while the "high lights" are building up during the development. By holding the plate still, and as even as possible, the picture develops evenly, and possesses far more fine details than when the solution is waved to and fro.

The subject could be expatiated on to a much greater length. In considering the matter, the day can be recognized when "secret processes" shall be no more; and while the *power of knowledge* shall be appreciated, the *power of manipulation* shall likewise be esteemed, for no man can take it from him who possesses it.

REGISTRATION OF DESIGNS.*

CONSIDERING the great number of articles only worthy of registration that annually appear on the patent lists; that many meritorious inventions are patented merely with a view to a public registration of priority of invention; that the whole business of registration can be done by post; and, above all, that a provisional registration, giving protection for one year, costs, in fees, only *ten shillings*, it appears to us to be a singular circumstance that the Designs Office is not more used. The advantage of giving a year's protection for 10s., and without agents' charges, ought to be a powerful argument with impecunious inventors. Looking to the great proportion of patents that are only provisionally protected, the neglect of the registration for the Patent Office appears the more strange. It is true complete registration, costing £10, only lasts three years. But neither does a patent, costing £25 in fees, and, with the agent's charges, often double, unless it be renewed for five years more by the payment of another £50. And how many come to this stage? Not one-half, while only three or four per cent. pass the Rubicon of the £105 at the end of the seventh year. Successful patents are mostly those of persevering people who re-patent improvements—often completely changing the original invention—suggested by practical trials. In the meantime, the £25 and the agent's fees are possibly heavy payments for a young man, while nothing would prevent him from patenting his completed invention after working under the protection of the three years' registration. It must not, however, be presumed that the registration of an article affords a protection of the same kind as that by a

* *The Stationer.*

patent; though a patent does not afford protection to a principle. By departing from little more than the shape the succeeding patentee may nullify the grant to a predecessor.

A number of Acts have been passed since 1787 for protecting ornamental designs; and in 1843 and 1853 similar protection was afforded to articles of utility. By them protection is given to the shape or configuration of any article, "whether it be for the whole of such shape or configuration, or only for a part thereof." It does not protect "any mechanical action, principle, contrivance, application, or adaptation;" nor the material of which the thing is made. But then, in very many cases, the mechanical action is absolutely inseparable from the shape. As at the Patent Office, so here, no warranty of soundness is given by preliminary examination. The principle of provisional registration is carried out in the Designs Office as well as at the Patent Office. A copyright for one year is given to the originator, as also to the proprietor, of any new design "for the shape or configuration either of the whole or of part of any article," the "shape or configuration having reference to some purpose of utility, whether such article be made in metal or any other substance." During the year the proprietor may sell the right of applying it, but must not, under penalty of nullifying the copyright, sell any article made according to the design. This can only be done after a complete registration, by which a copyright of three years is given to the author, under the same terms as for the provisional registration. Briefly, provisional registration gives the right of selling the design, but not the article made according to the design. By a special order of the Board of Trade the time of the provisional registration may be lengthened by six months, making eighteen months in all. The amount of novelty required is, that the design must not have been published in at least Great Britain. The fee for provisionally registering a design for one year, affording protection during sale or putting to work, is only ten shillings; the fee for complete registration for three years is ten pounds.

On sending the money by a Post Office order, together with the design and description, to "The Registrar of Designs, Designs Office, London, S.W.," provisional or complete registration can be at once obtained. Any communication or inquiry similarly addressed is at once responded to. The Registrar has to be furnished with two exactly similar drawings, with a written description, with the title of the design and name and address of the person claiming to be the proprietor. For the drawings and descriptions there is a regulation maximum size of 24in. by 15in., with a blank space left on one of the sheets of 6in. by 4in. for the certificate. Every article registered must be marked as such, but a penalty is imposed on so marking a new article after the expiration of the registration. The drawings of the designs for which the registration is expired can be examined; but with unexpired designs this can only be done in the presence of the Registrar himself, and copied solely under a judge's order. We may mention that, in several important patent cases, the registry has been lately successfully searched with the view of proving prior publications.

There can be no doubt that the Office for Registering Designs would acquire very much greater importance if it afforded protection without instantaneous publication. In this way it contrasts unfavourably with the Patent Office. Ornamental designs are not open to the public until their expiration, but useful designs are. If only one month of secrecy were granted, time would be afforded to an inventor to look about him, and determine whether his invention might be worth a patent. Registration would thus, at less expense, take some of the main functions of the provisional protection of a patent. Another drawback is, no doubt, the fact that only one shape of the same thing can be registered. This also evidently limits the safe employment of the office in some cases.

Correspondence.

HINTS TO PORTRAITISTS.

DEAR MR. EDITOR,—Will you kindly read first, and open the enclosed after; there is something inside got out of the fog. I fancy I hear you exclaim, "Fog? Do not talk about fog, unless you wish to drive a photographer's brain to desperation!" Well, of course, you know how very foggy it has been for a very long time.* Do not throw away my letter, or cast it into that dreaded basket. Why should that word fog so arouse your ire?

There is something to be got out of fog, though it might have been next to hopeless for us to have got clear of it of late. Indeed, I have often asked myself the question, on seeing the landscape upon my chamber window most fearfully fogged, Is it any use lighting my stove to-day? This has not been the only thought of perplexity I have had to battle with; they have come upon one thick and fast, for it has been a time for thinking, and thinking is good; we should not waste time, much less kill it. Well, in this time of thought, I asked myself whether I could do anything to help on others who might still be surrounded by fog, even when the beautiful spring shall dawn upon us once again? And, do you know, I found there was light enough coming into my mind to make an impression, in spite of an atmosphere through which I could give it you for those who deal in light, for I am one who believes in letting light shine for others free as it comes from heaven. I thought if anything could be done to give the art a fresh start it would be a great boon for many. This led me to think, and I send you the poor result, and hope to send better still.

Now you can open envelope, in which you will find a *carte* and a bottle, out of the fog; the *carte* is to help in bringing gold, the bottle to keep comets in. There is a little colour in the face of the portrait, without a touch of a

brush upon the surface, enough to take away the coldness sometimes found fault with.

I will explain—not see—my neighbour's defects across the road, and well too, for I could exercise myself with my own faults. No studio bell's incessant call compelled me to see to my plates being clean, or keep me from cleaning my own. No sitters, no babies kept me under glass; I was free, and at liberty to ask myself a few questions, which, at times, is a good thing; good to turn over all one's troubles, to look them through, and try again to master them. Fog should not stop this warfare.

Yes, Mr. Editor, there is no such thing as darkness in this world without light. There is always light if we would remain long enough in the dark to see it. Well, I have got some light out of the dark fog days, and I will all if you think it work while some other time; but the bottle, I think, will be useful to all. It is a bottle within a bottle, for the use of collodion or varnish, and is valuable in keeping back sediment, which so often comes out upon the glass, causing trouble in every print. I made it by grinding off the bottom of the small bottle, and the top of the larger one, using two corks for the purpose of emptying when requisite.

At all events, whether good or bad, take the will for the deed, and believe me, with many thanks, for light received from the PHOTO, yours sincerely,
G. R. GILL.

PAPER IMPERVIOUS TO MOISTURE.

DEAR SIR,—The following is the recipe for the size to be applied to prints on plate paper, so that they may be coloured:—

To a quarter of a pound of best parchment cuttings add two quarts of water and a piece of curd soap about the size of a thimble; let it simmer over the fire two hours, keeping it skimmed; strain it, and add two quarts more water, in which one and a-half ounces of alum has been dissolved. It will be about the thickness of cream when cold.

When used, make it hot, and, with a large camel's hair brush, pass over the face of the print, taking care that every part is covered with as much as it will absorb; then spread the prints out to dry.

In the case in which I had made the prints so very non-absorbent, I had used an excess of alum.

I notice that Mr. Bovey also considers the matter important, but is of opinion that if the paper is made impervious to moisture it will interfere with the production of vigorous prints, and gives his reasons, in which, I think, there is force. Nevertheless, if the advantages in other respects would be great, is it not worth while making some experiments to test the matter, with a view of overcoming any such want of vigour?—Yours truly,
WILLIAM MONKHOUSE.

Lendal, York, March 6th, 1871.

REDUCING A BATH TO CARBONATE OF SILVER TO PURIFY IT.

DEAR SIR,—Amongst the many valuable articles contained in the YEAR-BOOK for 1871, is a method of curing a disordered negative bath, by Mr. W. Brooks (I believe the plan was first proposed by Mr. Gage).

I followed out the instructions of Mr. Brooks, with somewhat curious results. About eighty grains of negative bath had been prepared, and, on trying a plate, a number of large star-like spots were formed. The bath was then allowed to rest some days, and deposited on the sides and bottom of the bottle a number of needle-shaped crystals of a deep purple colour. These crystals adhered so tightly to the bottle that they could not be removed by violent shaking. The bath was again filtered and tried, and then gave plates covered with myriads of small pinholes; in fact, just the appearance of a bath supersaturated with iodo-nitrate of silver.

The bottle with the purple crystals adhering to it was filled up with water, which soon became of a deep purple colour, although the quantity of the crystals is not sensibly diminished.

I shall be glad to learn if any of your readers, having tried the plan, have obtained similar results.

I enclose some of the crystals for your inspection, and remain, dear sir, yours truly,
A. W. H.

Dublin, March 1st, 1871.

[The result is curious. Have any of our readers had experience with this method?—Ed.]

* This letter was received before the recent prospect of spring weather commenced.—Ed.

SELENEGRAPHY.

SOME REMARKS UPON THE NATURE OF LUNAR LIGHT.

SIR,—I remarked in the number of your journal for December last a letter from Mr. Baxter addressed to the *Philadelphia Photographer*, in which he affirms, in reference to the moonlight effect secured by Messrs. Robinson and Cherrill, that the production of a moonlight landscape by means of photography is impossible, and that an image only of the moon itself can be obtained. This statement, coming apparently from a man well versed in the study of physical science, merits particular attention, and I have taken upon myself the task of removing Mr. Baxter's error, seeing that I have proved by actual fact that it really is quite possible to produce a photographic landscape during the night with real moonlight effects. As it is probable that Mr. Baxter has not seen the different articles which have been published in your journal, I have sent copies to him, as also to the *Philadelphia Photographer*, accompanied by proofs obtained by me in July and August last.

As the question is one of importance, perhaps you will allow me to make a few speculative observations on the subject in your journal. In the first place, then, let me ask, is the moon merely a screen, so to speak, or a reflector of the light of the sun? I think that there can be no doubt it must possess, besides, a certain illuminating power of its own, from the fact that its light impresses the sensitive plate the more readily the greater its distance is from the sun. Thus the image is more powerful at ten o'clock than at nine, and at eleven again than at ten, the time of exposure diminishing rather than increasing. The luminous lunar rays, if but a reflection, would reproduce the same elements as those of the sun, but in a less degree; but this we find not to be the case, for the sensitive plate reproduces, under the influence of lunar rays, colours which sunlight reproduces with great difficulty, as, for instance, yellow. If the illuminating power of the sun produces an image which is for the yellow 110 times less intense than for the violet, how is it that the moon, whose illuminating power is many thousands of times less than that of the sun, reproduces equally yellow and violet? Moreover, the moon ought to produce the photographic image in a proportionate space of time to the sun—that is to say, two thousand or ten thousand times more slowly; but this is not the case, for while the impression is produced in a quarter of a second in sunshine, with the same apparatus, and a similarly prepared plate, twenty minutes suffice to secure the so-called lunar reflection, instead of exactly 666 hours, or 23 days, which would be necessary if, as it is affirmed, the sun's rays are actually ten thousand times more intense than those of the moon.

Every one knows that by means of the wet process it is possible to allow an interval of three-quarters of an hour to elapse between the sensitizing of the plate and its development. I have obtained on the island of Sark, at a temperature of 78° (Fahrenheit?), some beautiful plates free from stains, sensitized and developed under the dark tent at a temperature of 50° (Fahrenheit?), and it is, therefore, equally possible to expose a wet plate for twenty or thirty minutes, especially during the night, such a pose being quite sufficient to secure a moonlight landscape.

In making this statement I do not deceive myself, nor do I deceive others, for my negatives will themselves prove the veracity of my remarks. A student of astronomy would be able to verify the duration of the pose by estimating the distance travelled by the moon, the dimensions of which are fixed upon the negative, and also the hour at which the proof was obtained by examining the height of the luminary.

I do not pretend, sir, that my experiments demonstrate that the sun unquestionably possesses a power of illumination of its own, but they prove, nevertheless, I think, that the rays of the moon, wheresoever they come from, are not many thousands times less powerful than those of the sun, as it has been affirmed.

Approaching a more general order of ideas, may I put the question, whether it is absolutely proved that all light sources emanate exclusively from the sun? On this point there is much to be said; the aurora borealis, electricity, terrestrial magnetism, the glowworm, inflammable gases, phosphorescent waves, the eyes of the lynx, the fur of a cat, crystal, and colours to a certain degree, as many other things, are either of themselves luminous and light giving, or derive the property from foreign influence. The moon is doubtless a combination of bodies having themselves individually a light of a particular nature and intensity, unknown at the present day, but of which photography appears to bear evidence. Why should not the moon, indeed, possess a luminous

photosphere, for is it not a planet, in all probability appertaining to the sun, like other planets?

It remains to be discovered whether it is the moon herself that throws out at one time luminous rays, or only reflections thereof, or whether it is the terrestrial atmosphere filled with luminous matter that voids ether, which becomes heated, cooled, magnetised, and luminous by friction, undulation, and vibration. Also whether the luminous rays or reflections of the moon, which arrive at our earth within the space of about a second, are not more actinic (better photographic agents) than those of the sun, which require eight minutes to traverse our atmosphere. And finally, whether the law of the decrease of solar light with the square of the distance is or is not modified in the case of the luminous rays from the moon; and at what height the moon must be employed as a photographic agent, in order to utilize it when less subject to the law of interference which obscures it; or at what point the rays emanating from the sun, and reperculated by the moon, cross under an angle less than 20°, as their undulations, crossing one another, increase materially in luminosity at this point.

If Newton has told us the truth, and if the moon, in like manner as the sun, sends its rays direct from the luminous body, it would be impossible to obtain a photographic image at night. But if Descartes, Huggins, Euler, Young, Wheatstone, and Fresnel are right in admitting that the undulations of the ether produced by all bodies visible at night, and of which the moon is the principal, give rise to the phenomena of light, then photographing at night, at certain hours, is possible—that is, under certain degrees of elevation, at certain periods, in suitable localities, and especially when aided by a luminous mirror (as in the case of a phosphorescent sea), when the magnetic state of the sky helps to multiply the luminous effect. The fixed stars and planets have also a considerable illuminating power, which may be added to the power of the moon. In Sweden, as is well known, the moonless nights are often so clear that it is possible to read by simple starlight; while in Russia, again, the moonlight is of extraordinary power; and if Russian photographers would only make experiment, they would be certain of definite results. I would, therefore, lay down a last hypothesis: the light of the moon is white—that is to say, composed of all the colours of the spectrum—and, this being the case, cannot its light be actinic, seeing that nitrate of silver is affected by it?

After having started so many speculations, I will finish by calling the attention of artists and philosophers to this fact: with a pose of twenty or twenty-five minutes, from nine in the evening till one in the morning, it is possible to obtain a landscape photograph during the night by the light of the moon, and of this I can afford ample proof.

If Mr. Baxter had confined himself to stating that the picture produced by Messrs. Robinson and Cherrill was not produced by moonlight, I should have said nothing, and the task of replying would have fallen upon Messrs. Robinson and Cherrill; but as he affirms that it is possible only to secure an image of the moon itself, and that a landscape photograph with real moonlight effect is out of the question, as the power of the moon is many thousand times less than that of the sun, I have taken up the pen to refute these arguments.

I hope shortly to be able to give you the details of my process, which is, indeed, so simple, that I cannot make out why it has not been discovered a dozen times since I had the pleasure of sending you my results. Being a Frenchman, I only await the end of the siege of Paris to divulge my little secret, and have contented myself, hitherto, with your testimony given in August last, as likewise that of my friends in Paris, that I have been the first to produce veritable moonlight landscapes by means of photography. As regards the splendid imitation pictures of Messrs. Robinson and Cherrill, I fully admit the difficulty of producing them; for, by using a method analogous to theirs, I find myself quite incapable of producing anything capable of comparison.—Believe me, &c.,

E. P. OGIER.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Association was held at the Free Library, William Brown Street, on the evening of Tuesday, the 23th ult., the President, Mr. THOMAS HIGGIN, in the chair.

On account of the illness of the Secretary, Mr. Murray, the minutes of the last meeting, not being produced, were taken as read.

The Treasurer's report for 1870 was read, and the accounts, audited by Mr. Wilson and Mr. Forrest, were passed accordingly.

Mr. GREEN drew the attention of the members to a paragraph in the *Athenæum* of the 18th ult., relating a curious experiment by Professor Seely, of New York, namely, that gun-cotton as prepared for photographers' collodion was not soluble in alcohol, but if a little camphor were added it dissolved at once. He (Mr. Green) thought that that singular fact might be of much importance to photographers, as it might enable them to dispense with ether, which, comparatively with alcohol, was a very unstable compound. It might also shorten the exposure by keeping the film of dry plates in a better condition for the action of the developer. He thought it might also act like oil of cloves and similar hydrocarbons in facilitating reduction of silver from its compounds, and, if so, might in that way shorten exposure.

A discussion ensued as to the functions performed by the preservatives for dry plates in general use, in the course of which Mr. HENDERSON stated his conviction that the action was as much chemical as mechanical.

Mr. PHIPPS sent for exhibition some photo-enamels kindly lent by Mr. A. L. Henderson, of London, which were examined with great interest, and much admired for their exquisite softness and delicacy of detail. It was explained that these, however, were by no means the best specimens yet produced by that gentleman.

A letter from Mr. Llewellyn Nash (a former member of the Association, who is now at Para) was read, in which reference was made to the picturesqueness of the neighbourhood. Mr. Nash offered photographic aid in that country, for which thanks were accorded to him.

Mr. WILSON read a letter from Mr. Flukes, of Bath, who volunteered to come down and exhibit in the lantern architectural views of Wells. The Society accepted thankfully the kind offer of Mr. Flukes, and Mr. Wilson was requested to communicate with him, placing the next monthly meeting at his disposal, when the members might invite their friends.

The PRESIDENT then read the paper for the evening, on Photo-Micrography (see page 113). The paper was illustrated with diagrams of the plans in use by Dr. Woodward and Dr. Maddox, and also that employed by himself. He also exhibited and explained a heliostat which had been constructed for him on the same principle as Dr. Woodward's.

Mr. HENDERSON, in moving a vote of thanks to the President, remarked that there was no evidence that the sulphate of copper solution had the effect of correcting the action of the lens. The lenses in use by the President were corrected for photographic purposes, and he used the copper solution likewise with success, whereas, according to the theory adduced, they would have been "de-corrected." He (Mr. Henderson) also thought that if the bleaching of the more opaque tissues of insects would destroy the more delicate portions, the better plan would be to take two negatives, viz., one of each portion, and print them by combination.

Mr. HUGHES, in seconding the motion, spoke of the careful manipulation required for work of that class.

The PRESIDENT exhibited a series of photo-micrographs which he had received from Dr. Woodward. They were chiefly microscopic test objects, and some of them were magnified to the enormous extent of 4,500 diameters. A "Pleurosigma angulatum," showing the course of a fracture, was remarkable.

The Excursion Committee were requested to report to the next meeting on localities deserving of a visit.

A discussion ensued as to the collodio-bromide process and the merit of its discovery. The opinion was, that since its discovery very little, if any, real advance had been made in the process.

Mr. LEWIS HUGHES said that he had recently developed six collodio-bromide plates which he had exposed eight months previously; they were all good negatives but one, which was a little under-exposed.

Mr. GREEN corroborated this by informing the members that he had kept a plate exposed in August until February, and that a good negative was then developed.

The consideration of the appointment of honorary and corresponding members was entered into. It was ultimately resolved

that the matter should be left to the Council to report on at the next meeting.

Mr. GREEN exhibited one of the cards put forth by the Stereoscopic Company, purporting to be a "pigeon letter" sent to Paris during the late siege, whereas it was quite illegible under any magnifying power. Many of the members who had been similarly deceived concurred in denouncing such a proceeding.

The meeting was then adjourned.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF LONDON.—The next meeting will be held at No. 9, Conduit Street, on Tuesday evening, 14th inst., when a discussion on the causes of injury to negatives from splitting of the film will be introduced by Mr. O. G. Rejlander. A paper "On Large Photographs" will be read by Mr. E. Dunmore. A series of dry-plate pictures will be exhibited by Mr. F. Beasley, jun., and two novel forms of copying camera by Mr. Rogerson, of Manchester.

M. ADAM-SALOMON.—This distinguished French photographer and sculptor, who has, during the siege of Paris, been a resident in London, returns with his family in two or three days to his home in Passy. He ascertains that it has suffered very little during the siege, his chief loss consisting of a favourite horse (a present from the Duke of Hamilton) and some domestic animals, which have been eaten. We are glad to state that his exile in this country has been lightened by the attentions of friends. He was spontaneously elected a visiting member of the *Athæneum* Club, and an honorary member of the Solar Club, during his stay.

PORTRAITS IN A GRADUATED TINT.—A correspondent says:—"I have just been looking over some Russian photographs, and am struck with a very good idea made use of in them, *i. e.*, a graduated light and shade from top to bottom of the picture, being a warm brown at the top, graduated down to the original colour at the foot. I suppose that it is effected by a graduated coloured sheet of glass laid on either before or after printing. Will you be good enough, through the columns of your journal, to explain the process, and say where we can get the materials? I have no doubt that it would be interesting to many of your readers, as the effect in photographs of sculpture, columns, &c., is very good." Can any of our readers give information on the subject?

FAME AND PHOTOGRAPHY.—In our time the path of glory leads to the photographer's studio, and monarch and murderer, hero and hound, find there, as in the grave, an equal platform. The famous greyhound Mastor M'Grath, which has added at once to the wealth and distinction of the Lord of Lurgan, has, in common with all celebrities, had to run the gauntlet of the studios. By order of Her Majesty, after she had inspected and fed him, he proceeded to Messrs. Hill and Saunders' atelier, and was photographed there; and, on another day, among visits to royalty, nobility, and clubs, we find a photographic engagement at MM. Mayall's studio in Regent Street.

THE COLLODIO-BROMIDE PROCESS.—Messrs. Horne and Thornthwaite have just issued a valuable little pamphlet by Mr. Henry Cooper, Junr., entitled, "Hints on the Collodio-Bromide Process." It contains very clear and concise instructions for working this elegant process successfully, and will, doubtless, aid in giving it a popularity which, from various causes, it has not yet attained; and this result will be materially aided by the selection of the requisite preparations which the same firm will supply.

REDUCING CHLORIDE OF SILVER.—Chloride of silver can be reduced by grape sugar, and this method affords a way for reclaiming photographic wastes, and of preparing pure metallic silver. Take 14 parts of well washed and still moist chloride of silver, 24 parts of caustic soda, sp. gr. 1.333, 11½ parts ammonia, sp. gr. 0.925; to this add, with constant agitation in a flask, 7½ parts pure honey, or 9½ parts grape sugar syrup, and let the mixture stand in a warm place, until sulphuretted hydrogen affords no sign of silver. Decant, and wash out all traces of chlorine. The reduced silver can then be dried, and melted in a crucible. Platinum black, finely divided metallic platinum, can be obtained from the chloride by adding carbonate of soda

in excess, and, after adding grape sugar, heating the solution for ten minutes. The precipitate can be collected in a filter, and then well washed and dried.—*Professor Joy.*

MORE INDECENT PHOTOGRAPHS.—During the week the police made another raid on Holywell Street, and seized a large number of indecent photographs and books. The accused persons, of whom there were several, were charged at Bow Street, and remanded.

IMPORTANT COPYRIGHT CASE.—An important copyright case has just been decided in Ireland. At the Nanagh Assizes, in Tipperary, Messrs. H. Graves and Co., brought an action against Mr. Tracer, for pirating the copyright of the engraving of the "Departure of the Pilgrim Fathers." Verdict for the plaintiff—damages, £100 and costs.

PARCHMENT PAPER.—Some improvements in the manufacture of vegetable parchment or parchment-paper have recently been patented in this country by an agent on behalf of Colin Campbell, of Buffalo, New York. By a well-known process, vegetable parchment is produced by passing common unsized paper through a bath of dilute sulphuric acid, the catalytic action of which changes the substance of the paper into an article resembling, in structure and qualities, ordinary animal parchment. Great care and delicacy are requisite for the successful accomplishment of the operation, which almost entirely depends on the strength of the acid, the temperature of the factory, and the length of time the paper is immersed. If the sulphuric acid is not sufficiently diluted, the material is charred. If, on the contrary, the solution is not of the necessary strength, and the paper is left for too long a time subjected to its action, the latter becomes partially converted into dextrine. Experiments have proved, however, that a much superior article can be manufactured by employing commercial sulphuric acid, or oil of vitriol, in an undiluted state; the new process, moreover, permitting the acid to be used in a cold state, and the operation to be carried on in a room at any ordinary temperature. Parchment-paper manufactured by this method retains its qualities after being wetted and dried; whereas that produced by the usual process, when treated in a similar manner, loses to a great extent its pliancy, and becomes hard and stiff. The invention to which letters-patent have been granted consists in passing the paper through a solution of alum, and thoroughly drying it previous to its immersion in undiluted acid, thus preventing any undue action of the corrosive principle of the vitriol. The patentee also claims, as part of his invention, the treatment of the paper with acid during its manufacture, by allowing the web, after passing the drying rollers, and with or without previous immersion in the solution of alum, to dip into a tub containing the acid, and then into a vat of water. The paper is afterwards passed through an alkaline bath, being subsequently treated with water to remove the acid. According to the inventor, written and printed paper may undergo this improved process without materially affecting the clearness and distinctness of the letters.—*Stationers and Bookseller's Circular.*

To Correspondents.

ADVICE TO CORRESPONDENTS.—We are at all times glad to advise our readers on any subject connected with the art upon which information can be given in this column; but to enable us to do so with efficiency, and without unnecessary waste of time and space, it is desirable that a few conditions should be observed by correspondents. All questions should be stated clearly, and written legibly on sheets of note paper, small scraps of paper and sheets of foolscap being equally unsuitable and inconvenient. Where several questions are asked, they should be kept distinct and numbered. Where processes and formulae have been stated in our pages, it is better for correspondents to refer thereto than to request us to do so, as we cannot, with fairness, occupy space by repeating formulae which have once appeared, merely to save a little trouble to individuals. Correspondents should use distinctive names or initials: such signatures as "A Subscriber," "An Amateur," and others of a general character being often adopted by a few correspondents in the same week leads to confusion.

MELBOURNE.—We believe that caustic potash will remove *tunicare* from used plates. 2. As we understand the Post Office arrangements, an invoice or bill can be sent with a parcel of photographs by book post, provided no note in the character of a letter be added.

H. C.—The collodio-bromide process has not been extensively worked in this country, nor, so far as we are aware, anywhere. We do not know of anyone who has worked it out according to the formula of Mr. Carey Lea. We have received from Mr. Lea some exceedingly fine photographs produced by himself by his own method. In our own comparatively limited experience with the process, we found it required about three times or four times the exposure of wet plates. 2. We hope, and believe, that the test between carbon and silver printing will be carried out, as it must be very interesting and instructive to many photographers, who are anxious to know the relative capacities of the two processes on the score of beauty of result. We have seen many carbon prints inferior to silver prints from the same negatives, but, on the other hand, we have seen many carbon prints which we preferred to silver prints.

W. P. COWING.—Yes; you can obtain the number. It is clear that the wrong number was sent by some mistake. Send it back, and the desired number shall be sent. Let us know if any further error occur.

W. W.—The small white spots with black centre are generally due to iron spots in the paper. When the fault is in the paper, you will generally be able to find some indication at the back as well as at the front of the print. 2. Washing in distilled water before toning is by no means imperative, and, unless your ordinary water is very impure, scarcely necessary. We, as a rule, wash very slightly, and in ordinary water, before toning.

E. ALLEN.—A background screen for vignette pictures should be of a light tint; grey or drab will answer best.

CHARMADY GHAUT.—Removing spirit varnish is sometimes a troublesome operation. It can only be done by the use of strong alcohol. Place the negatives in a dish covered with the alcohol, covering the dish with a plate of glass to check evaporation. When the resin is softened, rinse repeatedly with alcohol. It is as well to run an edging of black varnish round the negative first. This will not be dissolved by the alcohol, and will check any tendency in the film to leave the glass. When the varnish has been removed, wash the film with water until it flows freely; then remove the iodide with hyposulphite solution. 2. From five to ten grains of gum-arabic per ounce will serve. 3. Unless the Autotype Company undertake such work, we do not know of any firm which undertakes carbon printing for the trade.

G. E.—Mr. Croughton, of 14, Church Road, Albion Road, Hammersmith, is an excellent retoucher of negatives.

W. WALKER.—We have not seen any of the Russian photographs of the kind you describe, nor do we know how the matter is managed. If you can send us a copy for examination we can possibly give an opinion. 2. Fluid ounces. 3. Into a dull light, yes; but it is better to avoid risk as much as possible.

J. R.—Bromide of potassium is very sparingly soluble in alcohol, and therefore, can only be used in very small proportion in collodion. The introduction of water into the collodion should be avoided. Use bromide of ammonium, or bromide of cadmium, which is more easily soluble in alcohol. To what formula do you refer as recommending bromide of potassium? The ether and alcohol you have used will, we have no doubt, answer.

IRON.—We do not know any manufacturer of iron sashes. If you have access to any journal devoted to gardening or horticulture, you will probably find the advertisements, as they are chiefly used for greenhouses.

A. W. H.—The result you describe is very curious. The purple crystals were chiefly in a state of black powder when they reached us. Had permanganate been used to the bath? We only once tried the plan, and with very excellent results.

LITHO.—In our YEAR-BOOK for 1867 you will find an article on the subject; and in our Volume for 1869 there is a series of articles on the subject of photo-lithography and photo-zinco-graphy.

1871.—The collodion in question will, doubtless, work with any good formula; but it may fairly be assumed that the formula which accompanies the bottle is especially well adapted to its qualities. 2. Boiling down a bath does not necessarily get rid of all contamination. It gets rid of organic matter, as a rule; but excess of iodide of silver may remain and cause pinholes, and an alkaline condition will, probably, remain, which the addition of a trace of nitric acid may remove.

F. BOSWELL.—The prints are duly registered.

Several Correspondents in our next.

IS PAPER A CAUSE OF FADING?—IMPERVIOUS PAPER.

IN a recent issue of this journal, one of our correspondents, Mr. Stokes, asked a very important question: Is the character of the paper used in photography a cause of the fading of photographic prints? And he argues, with some reason, that, as negatives composed of reduced silver do not fade, neither should prints of the same metal, unless the substance—paper—with which the metallic image is in contact, were in fault. If the paper be in fault, the defect may either proceed from something in its constitution of a deleterious character, or from the fact that its porous character, unlike that of the glass supporting the collodion image, permits the ready access of moisture and impure air to the image; and assuming that the porous and absorbent character of the paper is a chief source of danger, Mr. Stokes asks if it is impossible to prepare paper impervious to moisture, and so get rid of a serious drawback on silver printing.

The enquiry generally is an interesting and important one, which has not hitherto received as much attention as it deserves. Fortunately, a tolerably definite answer can be given to both Mr. Stokes's questions. The paper undoubtedly is a frequent cause, directly or remotely, of the fading of prints; and paper impervious, absolutely or partially, to moisture can be prepared for photographic purposes. Unfortunately, the subject comprehends more than is involved in these answers. Any aid, however, to the securing of permanency in silver prints is of the deepest importance, and it may be interesting to enquire into the sources of stability in negatives, and ascertain how far the same conditions may be secured in paper impressions. The first question to be decided, however, should be whether the negative is absolutely stable—or, rather, under what conditions it is stable. Apart from abnormal conditions, such as cracking, a negative is permanent when it is protected by a waterproof varnish from air and moisture. A silver image on collodion, whether positive or negative, exposed to the atmosphere without protection by varnish, very rapidly becomes tarnished by the action of sulphur and other sources of atmospheric action, but not so much or so disastrously changed, perhaps, as an albuminized print, because the conditions vary. There is in the negative a much greater body of silver than in a paper print, which, of course, resists such action as would produce fading, surface discolouration alone taking place. The collodion on which the silver image is formed, resting on glass, also protects the negative from all atmospheric action except that which reaches its surface, and thus affords another element of safety to the negative, of which the ordinary paper print is quite destitute; and

the negative, when properly varnished, may be said to be protected from all outward injurious agencies.

The negative owes its stability, then, to the simple fact that the susceptible substance of which it is formed is thoroughly protected from the deleterious agencies to which the silver print is exposed. The glass at the back of the film and the varnish on its surface protect the silver alike from moisture and gases. And in such degree as the silver print can be placed under similar conditions, its permanency may be anticipated. That this is so, is in accordance with experience as well as analogy. Paper negatives which are thoroughly waxed are quite permanent, whilst unwaxed paper negatives are apt to change. Prints treated with wax and encaustic pastes preserve their pristine beauty much better than those which receive no such treatment. Mr. Blanchard's method of treating prints on both sides with collodion was proved, beyond a doubt, to exercise a most beneficially protective influence. So with varnished and French-polished prints. The one thing required to make a carefully produced silver print absolutely permanent is some means of rendering it impervious to moisture and atmospheric influences, without, at the same time, detracting from its beauty.

Without at present considering how far the sizing of the paper, or the albumen on its surface, contributes to instability, we may for a moment glance at the methods of rendering paper impervious to moisture, and the value of such quality in securing stability. Methods of rendering paper impervious to moisture have frequently been devised and frequently patented. In 1853, Henri Joseph Scoutetten patented a method of rendering paper impermeable for photographic purposes, which consisted in immersing it in a solution of india-rubber or gutta-percha in purified sulphide of carbon, and then rolling thoroughly. Five years afterwards, Mr. Alonzo G. Grant entered a provisional specification, describing a method of rendering paper for photographic purposes insoluble by means of a solution of india-rubber and other resins; and a method was patented by Mr. Sutton for rendering the paper impermeable by means of india-rubber previous to albuminizing. In 1855, Mr. Mayall patented a method of preparing a substitute for paper for photographic purposes, which was a form of artificial ivory. In the specification various modes of producing such a substance are included; but amongst other things we find sulphate of baryta and albumen, or gelatine, made into sheets or slabs, and rendered insoluble. This process was given up because the material, although insoluble, absorbed and retained the various salts employed in solution with great tenacity, and was altogether unmanageable. It was impossible to get rid of the hypo, and the pictures were far from permanent. Four or five years ago a method of preparing paper possessing many advantages was patented in America and in this

country by Mr. Brinckerhoff. A preparation of kaolin or sulphate of baryta and gelatine was applied to the paper, after which it was treated with a solution of alum, tannin, or other suitable substance, to render the gelatine insoluble. The result was a hard, smooth, pure, white surface, not readily permeated by aqueous solutions, giving a very pleasing texture to the finished photograph; in our estimation much more pleasing than the glossy surface of albuminized paper. Although the paper possessed many advantages, and was introduced to photographers ready for use, it never came much into use. Last week we published a letter from Mr. Monkhouse, giving a method of preparing impervious paper, based on somewhat similar principles. The method employed in this country of securing a hard surface in the manufacture of paper is analogous: the paper is sized with a solution of gelatine and alum, and in proportion to the quantity of the size employed, the paper becomes hard and impervious to moisture, and so varies from the softest and most bibulous samples to the finest vellum surfaced paper. One of Mr. Swan's patents includes a method of preparing paper with a coating of gelatine rendered insoluble by means of chromealum. The well-known method of parchmentizing paper by means of dilute sulphuric acid renders it impervious to moisture, and the difficulty hitherto felt from the harsh and intractable character of parchmentized paper has recently been met by Mr. C. Campbell's patented method of using undiluted acid, by which pliancy and smoothness are retained. It will be seen, then, that methods of rendering paper more or less impervious to moisture abound, and that some of them are well suited for photographic application. In the methods in which india-rubber was employed, the coating was so slight that moisture was not repelled. Brinckerhoff's paper was highly impervious to moisture, but not sufficiently so to interfere with photographic operations. The results it gave were in every way pleasing; and the patent having, we believe, expired, the process is now open to the public.

How far the prints were more permanent on such paper we cannot state, as we have no data upon which to form an opinion. *A priori*, there is every reason to believe that the less permeable the paper, the less the print is likely to be subject to deleterious action. All the solutions will be more readily washed from non-absorbent than from absorbent material; and the more impervious the paper in the finished print, the more nearly it must approximate to the condition of the stable varnished negative.

CAMEO VIGNETTE PORTRAITS.

ABOUT twelve months ago we described a very pretty novelty in portraiture, several examples of which had reached us from Italy, and, in the absence of any specific or descriptive name, we styled them, in an article on the subject, cameo-medallion portraits, and strongly recommended them to English portraitists, as easily produced and very effective. Subsequently we reproduced in our pages an article by Carl Orziwanek on the subject, who stated that the style was becoming popular in Vienna. Curiously enough—and, as we think, unfortunately—novelties are not readily welcomed in this country if they involve effort or enterprise. We have pleasure in announcing that facilities are now provided which will render the introduction of the novelty in question easy to English portraitists, and that, besides facilities for producing them, an important inducement will exist in the possibility of obtaining examples of the new style. "Things seen are mightier than things heard;" and it is doubtless true that the mere description of a novelty may fail to impress many with its value. Messrs. Marion, of Soho Square, have undertaken the introduction of the style to which we refer, under the title of "Cameo Vignettes," and to provide all the necessary aids for their production.

The cameo vignette is of the usual card size, containing

a vignetted head and bust, or three-quarter length, preferably the former. After vignetting, an oval mask is laid upon the figure and vignetted portion of the background, and the margin exposed so as to print a deep black, forming a dark border round an oval aperture containing a vignetted image. This is finished, trimmed, and mounted in the ordinary manner. After this it is subject to pressure under an oval convex die, like that used for the "diamond cameos," the die being, of course, of precisely the same size and shape as the oval mask which protected the image whilst the border was printing. The size of the oval in the examples before us is, in the major axis, about three inches, and in the minor axis two inches and one-eighth. The white edge of the mount surrounding the black framing the image is about one-eighth of an inch broad.

The general effect of the picture is striking as well as novel. The convexity of the mount gives the effect of relief with which many of our readers are familiar, and which is seen in enamel portraits on the well-known convex tablets. Indeed, these portraits in many respects very closely resemble ceramic portraits, in the appearance of delicacy, force, and finish. The especial advantage to be gained by the deep purple brown or black of the border is the peculiar delicacy conferred, by the force of contrast, on all the half-tones and shadows in the image itself, and gives much value to all the lights, and such especial delicacy to the flesh. The very deep-tinted spandril gives an effect of brilliancy to the lights, and extreme tenderness and delicacy to all the shadows in the image, although the picture is printed sufficiently deep to secure vigour and force.

We have received a number of examples of this style from Messrs. Marion, by different photographers, some by Rabending, of Vienna, and some by Messrs. Hill and Saunders, being especially charming. We are indebted, also, for a number of examples, not less charming, to Messrs. Vandyke and Brown, of Liverpool, who speak in high terms of the promise of public favour which the new style is likely to command. The increased charge which they propose to make is five shillings extra upon each dozen of cards. We think a higher charge would be cheerfully paid by the public for the greatly superior result produced. As, however, there is no form of taxation in the form of patent or registration dues, the increased cost consisting in a little extra apparatus and a little extra trouble, each photographer will determine this point for himself; but it will be wise not to make the new style too cheap. Messrs. Marion, as we have said, provide all the facilities, amongst which is an ingenious press, with various dies, and suitable counters, masks, fittings, &c. These are, however, matters of detail into which we need not enter, but we may remark that all who have the presses used for "diamond cameos" will need only some slight alterations, and an oval die sufficiently large for a single image on the card; all photographers requiring some novelty to stimulate business will find this well worthy of attention. We commend it strongly to portraitists generally.

THE RECENT ECLIPSE.

It is much to be regretted that as yet no complete or official report of the British eclipse expedition has appeared, or, indeed, seems likely to appear. Little by little, the accounts of the proceedings come out—now one gentleman detailing his experiences, and now another—so that possibly, if we only wait long enough, and carefully study the whole number of scientific and technical periodicals which are published from time to time, a full description of the observations and the results may be collected. If the expeditions had all of them proved unsuccessful, one would have thought the best policy would have been to have frankly admitted the fact; or, if important results had been obtained, then these should have been

published, with some sort of authority. As it is, however, every one who has taken part in the affair seems to have published a few incomplete remarks in reference to his own peculiar duty; and we are thus in ignorance whether certain data furnished by one class of observers are confirmed by the results of others.

In making these remarks, we do not in any way wish to throw blame upon any of those gentlemen who have narrated their personal experiences for our benefit; on the contrary, if they had not come forward with their accounts, we should have been without any information on the subject at all. We cannot, however, help thinking that there should have been some collective report, short and concise, drawn up by those who managed the expedition. There seems to have been some sort of organization as regards the disposal of the observers and the choice of stations, but here the matter apparently ended, for, their task accomplished, every one appears to have gone his way, and to have treasured up his experiences for his own special and individual benefit; so that, after a few brief and hurried telegrams, all we hear of the affair is from some disjointed reports, contributed by individual observers, and printed in the various journals.

Moreover, we must not forget that the expense of the expeditions—which was, as we know, extremely heavy—was borne entirely by the country, and this, surely, is another reason why an equivalent of some sort should be rendered in the shape of an official report. Besides the three thousand pounds liberally allowed by the Chancellor of the Exchequer, there must be taken into consideration the value of Her Majesty's ship *Pysche*, whose loss occurred whilst conveying a party of observers to Sicily; and one would have thought that for the credit of the expedition, therefore, those in charge would have rendered up an account to the public.

But it may be asked: Who is to do this? Upon whom does it devolve to collect and digest the data obtained at the cost of so much time and money? Obviously upon those gentlemen, we answer, who had the direction of affairs and the disposal of the money grant. If there was no committee, there surely must have been a directing body who decided upon the distribution of the funds, and to these we naturally look for an account of their stewardship. This may, of course, still be forthcoming, and we sincerely trust that such is the case; but we must remember that already three months have nearly elapsed since the date of the eclipse, and as yet no signs of any report have been seen. For it must be borne in mind that a communication of this kind requires but little time to prepare, seeing that what we desire is not the elaboration of any theory, or speculative explanation of results obtained, but simply an account of the observations made, and a statement of the conditions under which the data were secured, so that we may be able to draw our own conclusions from the evidence afforded.

It is, indeed, strange that this country, so especially noted for its special correspondents and high-class journalism, should have been indebted to foreign journalism for the first circumstantial account of the expedition. The interesting description given by Dr. Vogel in the *Mittheilungen*, and reproduced in these columns, was certainly one of the very first, as it was likewise the best account of the manner in which the expedition was organized and the duties apportioned; and if the worthy doctor had been fortunate enough to have had favourable weather, we might safely have relied upon him for a clear and systematic description of the proceedings.

We are glad to find that the photographs taken by Lord Lindsay's party in Spain are much more perfect than was at first supposed, some examples exhibited last week at Burlington House, on the occasion of the *soiree* of the Royal Society, being, indeed, very perfect.

AMERICAN CORRESPONDENCE.

SALTING THE COLLODION—PHOTOGRAPHY AS A BUSINESS—“THE YEAR-BOOK OF PHOTOGRAPHY”—THE ALCOVE BACKGROUND—SIMPLE CONTRIVANCE FOR GRADUATING THE BACKGROUND—THE ECLIPSE.

Salting the Collodion.—You are, no doubt, often amused at the stress laid by some upon the proportions and kinds of salts best to use in making up collodion. One will advocate cadmium most stubbornly; a second, potassium or ammonium; and a third, the most sensible of all, a mixture. It should always be borne in mind that the metallic bases of the salts used have no direct influence upon the sensitiveness of the collodion or on the beauty of the results. On the contrary, the amount of iodine and bromine in the collodion is of first importance, and so long as a sufficient measure of these in the proper condition is supplied, the results will be satisfactory. The matter came up before the Pennsylvania Photographic Association a month or two ago, and quite a discussion followed, when Mr. Charles Evans volunteered to make actual experiments bearing on the subject, and to state the results. Thereupon, at the last meeting of the Association, he exhibited a series of very interesting negatives, and prints therefrom, and read a paper, from which I make a few extracts, because they throw light upon a subject which, although not new, is often forgotten. Mr. Evans says:—

“I find the different salts used to sensitize do not, weight for weight, contain the same amount of iodine and bromine, so that one salt will produce a smaller amount of iodide or bromide of silver in the film than another. Taking the formula of ammonium and potassium as the standard, we have in 5 grains of iodide of ammonium 4.38 grains of iodine, and in 2½ grains bromide of potassium 1.68 grains of bromine. Collodion salted with the above, with a 40-grain bath, gives us good results, and may be considered always reliable. Many sensitize with the other salts in the same proportions as the above, without reference to the fact that they vary in the amounts of iodine and bromine they contain; they therefore do not produce the same results as with the formula of ammonium and potassium. Take iodide of cadmium, for instance, 5 grains of which contain only 3.47 grains of iodine, being .91 grains less than in the iodide of ammonium; therefore, in using cadmium, if we wish to maintain the same strength, its quantity should be proportionately increased, as observed in the standard formula; so in the use of bromide of cadmium, 2½ grains of which contain 1.47 grains of bromine being .21 grains less than in the same amount of bromide of potassium. The iodide and bromide of magnesium contain more iodine and bromine than any of the salts, and smaller proportions can be used. Ammonium, potassium, and magnesium collodions lose their sensitiveness in a short time, cadmium alone being an exception, producing a collodion which will keep for months, giving good results.

In order to show the different effects when the various salts are used in the same quantity, without regard to their proportions, Mr. Evans prepared several collodions, using the same iodide, but different bromides, and made negatives with each at the same time, with the same bath, and the same developer. The negatives and prints were produced, and the difference in result was remarkable. I enclose you the four prints which he exhibited. With—

- No. 1 bromide of magnesia was used.
 - No. 2 " potassium
 - No. 3 " cadmium,
 - No. 4 " ammonium and potassium,
- collodion six months old.

The effort was made to secure the comparison of effects upon the drapery rather than on the face; and, by comparing the four, you will find in No. 1 much better detail than in any of the others, although No. 2 nearly equals it. No. 3 shows a great falling off in quality, while No. 4

made with old and insensitive collodion, shows an immense loss of detail, due to the lack of sufficient bromide in the collodion. The study is an interesting one, and the matter should be borne constantly in mind when working in the studio.

The following table gives the proportions of iodine and bromine present in each of the salts used:—

250 grs. iod. of magnes. contain	228½ grs. of iod.
" ammonium "	219 "
" potassium "	191½ "
" cadmium "	173½ "
250 grs. brom. of magnes. cont.	217½ grs. of brom.
" ammonia "	209 "
" potassium "	168 "
" cadmium "	147 "

Photography as a Business.—I was not at all surprised to see you advocating the advantages of considering photography in its two great spheres—as an art and as a business—so warmly. In America, in former years, photography was regarded too much, I fear, as a business; but since the organization of our grand National Photographic Association, and the inauguration of its annual exhibitions, photography as an art has made rapid strides, and caught up with its companion, so that the two walk hand-in-hand. And when a new thing is offered, the question is not only asked, "Will it pay to make it?" but "Is it beautiful and artistic?—will it degrade our art and retard its progress?" Hence these two elements characterize the deliberations of our Association, and occupy the minds of our fraternity at large. Our photographic journals, too, must take part in, and sides with, both these objects of their patrons; and their editors are expected to help bear the business battles of the craft as well as to supply them with matter to guide them in their manipulations—to be awake alike for the interests of the store-room and the studio. With us, our country is so wide that our six or seven thousand photographers must be more or less isolated, for they are everywhere, from the top of Mount Washington down to the depths of Mammoth Cave, and among the rainbows and spray of Niagara; and this fact renders them often an easy prey to the vulturous process-monger and the dealer in quack requisites. The journal which such take is, therefore, expected to keep them forewarned and informed as to all that pertains to the interests of its readers. We find the two elements to work well together here, and the "dignity" of our societies does not suffer from the closest admixture of them.

THE YEAR-BOOK OF PHOTOGRAPHY.—As fresh and full of good as ever, it comes to us in due season, an ever welcome visitor. It seems to have exceeded itself this year, and I find in it many admirable things which I wish all could read. There is one advantage which a year-book has over a journal. It is the occasion of a grand annual re-union of photographic authorship, while the other is merely a small gathering, which, coming often, is not so generally attended. Once a year we hear from many good men in the art whose talent we are conscious of, but who will not be coaxed to write more than once a year, and then they write for the *YEAR BOOK*. A grand *table d'hôte* you give us this year, and let us all be refreshed and strengthened by it.

By the way, your *YEAR-BOOK* has a good sale in this country. A few days ago I found, just arrived, one thousand copies in one place, and three hundred in another. I hope it is abundantly appreciated at home.

The Alcove Background.—A few days after M. Salomon's alcove background was described by you in the *Philadelphia Photographer*, Messrs. Gihon and Thompson, one of our most enterprising firms in this city, had one erected. It answers admirably for all you have claimed for it, and an inspection of, and actual trial with it, enable me to say, that it gives the photographer wonderful power over (under) his light, so that he may drive it where he will upon the subject. Mr. Gihon tells me that his background cost him a great deal of toil, being a new thing to him; but he feels rewarded

for all his pains fully. He made the framework as you suggested, and covered it with thin pine wood, such as is used here for backing in picture frames. On the inside, over this, he placed stiff paper, which he covered with flock-grey, red and blue mixed, which gave him a very desirable tint; otherwise the construction is the same as M. Salomon's.

Simple Contrivance for Graduating the Background.—Mr. R. Benecke, of St. Louis, has shown me some very desirable effects secured with a dark background, by moving over it at one side during exposure a little triangular-shaped screen. The contrivance is merely a light wooden triangular frame covered with white paper. It is moved up and down without stoppage during a part of the exposure, behind the head of the subject, by means of a handle. Being of this shape, sharp lines are prevented. In this way a dark background may be lighted up, and a regular effect of gradation is the result.

I have seen Mr. Black, in Boston, use a similar contrivance, and both his and Mr. Benecke's pictures prove its excellence.

The Eclipse.—I suppose by the time this reaches you the eclipse will have been almost forgotten. You have, no doubt, received from Dr. Vogel some account of his fruitless expedition. I know full well what his disappointment was. We have some cheering news, however, from the party who were at Jerez, Spain. Mr. Willard, who was with us in Iowa in 1869, got one good coroual picture, showing structural lines. How our English brethren in the same neighbourhood succeeded I have not yet heard. It is to be hoped that after the wonderful sacrifice made by the English Government to fit out an expedition success resulted.—Very truly yours,

EDWARD L. WILSON.

Philadelphia.

COMBINED IRON DEVELOPER.

BY B. J. EDWARDS.

So much has been written and re-written concerning development with iron, and such an endless variety of modifications have been suggested, that it would seem almost impossible to say anything new upon the subject.

I have tried, and abandoned, an immense number of different formulæ, including most of those in which organic matter, such as sugar or gelatine, is used; with regard to the latter substance, I have, in every instance, found it a positive disadvantage. Perhaps the best and simplest developer known is the old fifteen-grain solution of sulphate of iron, but it should be used the third day after it is mixed, when it is in its best condition. This is the plan adopted by one of our most distinguished art photographers. If this solution be used freshly mixed, it is apt to fog; if too old, it will be found too weak to develop the delicate half-tints of the negative. The iron solution keeps much better in a concentrated condition, but a simple saturated solution of sulphate of iron soon acquires the property of rapidly decomposing when mixed with water in the proper proportion for use, otherwise there are many advantages in keeping. The ingredients which form the developer in a concentrated solution which shall be always ready for use. I have found that the saturated solution of iron can be so modified that it will keep indefinitely, and with it developers suitable for every variety of subject and condition of light can be made at a moment's notice.

To a professional photographer this is a matter of considerable importance, inasmuch as the suitability of the developer will depend, to a great extent, upon the complexion and dress of the sitter, and, in the case of children, upon the amount of exposure the plate has received. The latter, I need scarcely say, is not always under the control of the operator.

It will be found that by the formula I now give, any required result can be obtained by simply altering the strength of the mixture. To make the saturated solution, take one pound of common sulphate of iron, and one pound

of the double salt of iron and ammonia, with about one ounce of sulphate of copper. Throw them together into a large jar, and add water (about forty ounces) to form a saturated solution; after agitating until no more of the salts will dissolve, allow the mixture to settle, when it will be perfectly bright and clear, and of an apple-green colour. This colour it will retain for any length of time, together with all its properties, as when freshly mixed. I have kept it many months, and have never known it to become discoloured, as is the case with a plain saturated solution of sulphate of iron.

When required for use take, by measure—

Iron solution	4 drachms
Glacial acetic acid	4 "
Alcohol	4 "
Water	8 ounces

This will make a capital developer for summer use. For quick pictures, or winter work, the formula will be—

Iron solution	1 ounce
Glacial acetic acid	1 drachm
Alcohol	4 drachms
Water	8 ounces

For instantaneous work a still stronger solution may be used with advantage; while for copying engravings, or where strong contrasts are desired, the first formula may be very much diluted.

It is a good plan to keep each of the above developers ready, and use them either alone or mixed in different proportions as required; by these means the developer may be adjusted in a moment to suit the subject or the exposure. If desired to intensify, which is seldom requisite, a little silver solution may be added to the iron developer; this can readily be done without forming a precipitate; or, if preferred, the plate may be flooded (without washing) with a fresh portion of iron developer without the addition of silver, in many cases where only a slight degree more vigour is wanted, this will be found the better plan.

I have hitherto been speaking of portraits, but this form of iron developer will be found not less useful for all kinds of landscape work; there is no danger of fogging the plates, with far less than the usual difficulty in obtaining the right intensity in the negatives, which, at the same time, will possess great delicacy of detail, both in the shadows and high lights. For distant views and cloud effects this developer is invaluable, some of the most delicate effects of distance with clouds being often secured with a fully exposed foreground on the same plate.

I have found, during the four years in which I have had it in constant use, that this developer is all that is required for every kind of work with wet plates. I have not tried it for dry plates, but think it would probably serve instead of the gelatino-iron developer for gum plates.

For other purposes I feel sure that those who try it will always use it, and I trust it will prove of good service to many, both amateur and professional photographers.

GERMAN CORRESPONDENCE.

ART AND PHOTOGRAPHY IN ITALY—STEINHEIL'S NEW LENS—ALBERT'S LITHDRUCK.

AFTER shipwreck and a solar eclipse, with a hailstorm as an accessory, I am safely back in Berlin, in spite of snow and ice. With such drawbacks the photographic result of my trip is, of course, of little moment, but we can always learn something if we only keep our eyes open; and, starting with this principle, I was able to observe many photographically interesting objects. It is said that Italy is the home of art, and it might be supposed that the youngest of the arts—photography—would occupy a position worthy the art-reputation of the country. But this is correct only so far as the past is concerned. The Italy of our day has no good artists. Raphael, Michael Angelo, Leonardo, Ghiberti, Guido, Reni, and a host of others, are

no more. The proud palaces of Sansovino have gone to decay. The former splendor of the old Roman empire offers a still sadder spectacle. Nothing is left but gigantic ruins, mutilated statues, and faded frescoes. But these mute stupendous ruins speak a language of tremendous power. They tell of deeds of heroism and horrible crimes, of pomp and splendor, as well as of the squalid misery of ancient times. They impress upon us this world's history more forcibly than large folios, and all those ruins still retain the lustre of the unreachd beauty of antique art.

The disciples of art wander amongst these ruins. They leave, and are elevated by their study.

Our own time, by its grand inventions, is far in advance of ancient Rome, still, in the realm of art, it fails to approach it. We are imitators, and must remain so, and may consider ourselves fortunate that photography has given us the means to reproduce the art-treasures of antiquity with inimitable fidelity. There is hardly an antique remnant which the camera (and it, too, is an Italian invention), has not delineated, and the photography of Italy is devoted almost entirely to this class of work.

Pictures of all sizes are offered for sale at fabulously low prices. Pictures 8 by 10 inches are frequently offered for twenty cents, and, withal, tolerably well executed. The fact that the cost of labour is exceedingly low, and that imperfect prints are sold without compunction (which, considering that the multitude possesses very little taste, is not to be wondered at), explains this.

To please the public taste, extraordinary and almost impossible things are represented. I saw, for instance, in Naples, a photographic picture of an eruption of Vesuvius; also a photographed ascension of the mountain, and an interior view of the Blue Grotto. An expert could see at once that these pictures were copies of drawings, but the public demanded them, and bought them. *Mundas vult decipi.*

Another kind of pictures with which a Roman photographer here made his fortune are moonlight views of the Coliseum. It has become fashionable to view the remnants of the walls of the colossal amphitheatre by moonlight; and it is easily understood that photographs by moonlight, to be taken home as remembrances, found a ready sale. The secret of their production has been explained long ago; a negative against the sun is taken, with very short exposures, and printed very dark.

Otherwise we must admit that architectural photographs of imposing size and excellent execution are made in Italy. Sheets of from twenty to thirty inches are nothing unusual. With the above-mentioned low prices a splendid finish cannot be expected; generally they are pasted on very thin cardboard; and frequently, in order, to facilitate packing, they are not mounted at all.

In portraiture very little is done; and, perhaps, of all the countries of Europe, Italy has done the least towards the advancement of photography. The education of the people is of a very primitive character. No wonder, then, that foreigners have usurped the business, and English, French, and German photographers have gained reputation and money.

As photographic productions of an extraordinary quality, the pictures of Mr. Braun, of Dornach, Alsace, must be considered. He had the courage to take direct pictures of the darkened frescoes of Michael Angelo in the Sistine chapel. He employed the plan proposed by myself, of throwing sunlight on them by means of reflectors, and the result is admirable. His sheets made by the carbon process have been published; they are very little known; but we will hope that, with returning peace, they will become more generally appreciated.

But, notwithstanding all the interest which Italy offers, the season for travelling was too unpropitious. The entire absence of all heating arrangements made even a moderate cold very uncomfortable. It is no pleasure to go to the dinner-

table of the first hotel in Florence with overcoat and furs on, and I felt very well contented to return over the snow-covered Alps to my cold northern home.

I soon reached Munich, and could not let the opportunity pass of calling on Steinheil, Albert, and Obernetter. I found all the three establishments in full activity. It made a most favourable impression on me, when coming from the lazy Italy which only lives in the past, to be placed at once in the busy present of the new-born German empire, where, in spite of war, flourishes art, trade, and commerce as never before. Theatres, concerts, balls are frequented as in the midst of peace. Gambetta, who, ten days ago, declared that trade and commerce were prostrated in Germany, that social life was dead, &c., should have paid a visit to a Munich beer saloon before making such an assertion; he probably would not have babbled such nonsense. Munich beer and Munich art are considered standard in Germany; perhaps both stand in "Consal nexus;" and hence we must not be surprised to meet here with some new discoveries in our art.

To these I must add a new wide-angle lens by Steinheil. The lens is particularly intended for taking pictures at short distances, and for copying drawings. It admits of the employment of small ateliers and short cameras. With every lens a prism is furnished (it serves to give reversed pictures, so far as right and left are concerned). In this manner negatives, which can be used at once for the Woodbury and Albert process, are obtained.

I have, in a previous letter, reported on Obernetter's Lichtdruck. Albert works for the war on a large scale. War maps and pictures of the war are made by thousands. The negatives, which necessarily must be reversed, are obtained by a very simple process. A negative is taken in the ordinary way, and a sheet of gelatine is placed on the still moist collodion film, and the plate left to dry; when dry, it is detached from the plate and made transparent by means of wax; an excellent reversed negative is made in this manner. The maps which are made from these negatives leave nothing to be desired. The direct printing on Bristol board must be considered as a great improvement in Albert's process. It obviates the tedious and expensive mounting. On chalk paper, pictures are furnished which are in no way inferior to silver prints. Formerly chalk-paper was affected by water. This has been remedied long ago. A slight coating of varnish makes the picture impervious to water, and gives to it, at the same time, a gloss equal to albumen paper.

Albert is indefatigable in his endeavours to improve his process. Numerous "light-printers" have since started, but to Albert remains the merit that he was the first to use glass plates as the foundation, and, at the same time, to use an intermediate film between the glass and the gelatine, in order to secure a more perfect cohesion. The former circumstance gave to his prints that remarkable fineness which neither Tessie du Motay nor Poitevin have ever obtained (both of them worked with metal plates). The second point gave to his plates an extraordinary durability. The other "light-printers" were only able to accomplish anything after these processes of Albert became known.

DR. H. VOGEL.

COOK'S PATENT CAMERA.

BY C. E. ELLIOTT.*

In bringing before you this evening Mr. Walter Cook's patent dry-plate camera, I think I may say it is a real novelty. Although, no doubt, there may be some who have long since had the idea of making a similar camera. But, be that as it may, I believe no arrangement like the one I am about to describe has before been published.

If one were asked to indicate the principles on which a perfect dry-plate camera for tourists ought to be constructed,

they would doubtless be indicated to be—1st. Compactness and portability. 2. The ability to contain a store of plates sufficiently ample for a day's work, without the necessity of using a dark slide for each. And—3. A ready and certain way of bringing each plate in rotation to the focus of the lens, and, after exposure, returning it to the place whence it was stored, all being done without the aid of tent, hood, or dark cloth of any kind. These were the problems which the inventor of Cook's camera set before him to work out, and, in the camera now exhibited, you will find that, not only have all these conditions been fulfilled, but some other features of value added to them.

The compactness of the apparatus is so great that, in a very small space, we have the following:—A strong mahogany box, which serves as a case or body for the apparatus; a bellows-bodied camera, fitted on a substantial baseboard, and capable of extending to many inches, the focussing being effected by a double rack-and-pinion movement; two fronts for single and stereoscopic lenses; a receptacle or space in which to pack leuses, focussing cloth, and even refreshments on a partially limited scale, together with a supply of sensitive plates, up to a dozen and a-half, more or less, according to the thickness of the glass, and all of them so arranged as to be manipulated by merely drawing up or closing a slide, each plate being mounted in such a manner as to preclude the possibility of its sustaining harm, either from contact with its fellows, or from the admission of a stray beam of light.

The cabinet is divided into four parts: the camera proper; a chamber in which to keep the lenses and focussing cloth, and other "odds and ends;" and the other two are filled with sensitive plates, which, as I shall hereafter describe, are packed closely together, yet without any danger of scratching or other damage accruing.

By a mechanical arrangement the plates are presented in rotation to the action of the lens in the camera, and, as soon as each one has been impressed, it is, by another mechanical arrangement, transferred to a lower compartment, an unimpressed plate from which is, in turn, added to the supply in the upper chamber. Thus, by the exercise of the most ordinary care and common sense on the part of the operator, each of the sensitive plates is presented in rotation, and *without fail*, to the aperture, where it will be in sharp focus, and, after exposure, consigned to the plate box underneath.

In the front of the cabinet is a door the size of the whole of the upper part, and which opens downwards. This "door," which is retained, by means of brass straps, in a horizontal position, forms the baseboard or bottom of the camera, on which the front that carries the lens travels, the body of the camera being "bellows" fashion.

The focussing glass is mounted in a frame which folds down in the front recess below the camera. When the focussing has been effected, the ground glass frame is turned down in its own resting-place, and the back portion brought into contact with the front by the simple act of revolving it on its hinges.

The subject having been selected, and both upper and lower receptacles charged with sensitive plates, the next operation consists in exposing them. For this purpose the front slide, or shutter, is pulled up as far as it will go.

When the exposure has been completed, and the lens capped, the front slide, which has been up during the whole time of the exposure, is now pressed down. By this act the plate which has just been exposed is carried down along with it, and is safely lodged in the lower chamber, from which no subsequent action of the front slide can again dislodge it.

There is another slide at the back, the action of which is the very reverse of the front slide; for, while the latter pushes the plate down, but cannot take it up, the former lifts up a plate from the lower compartment to the upper, without having the power of again carrying it down. Thus, to ensure the harmonious working of the parts, the operator

* Read at a meeting of the South London Photographic Society, March 9.

should get into the habit of always pulling up the back slide, and pushing it down again before he takes a picture. Those who have had the camera in use aver that there is never a hitch or miss in its successful working.

From the foregoing description, the mode of construction and working of this, the latest addition to our photo-mechanical resources, will, I trust, be apparent to everyone present; and that an invention of this kind is destined to prove serviceable to tourists, no doubt whatever can be entertained.

The camera now before you has not been brought to its present perfection without many misgivings that it would never be complete, as one difficulty after another cropped up. I may mention one great obstacle, which I feared would militate against the adoption of such a camera by dry-plate workers, viz., the way in which we protected the film from being scratched. It was thus:—A piece of cardboard the exact size of the prepared plate had the centre cut out, leaving a margin all round one-eighth of an inch. The frame of cardboard was placed on the prepared side of the plate, and the back of the plate brought in contact with a piece of pasted paper somewhat larger than the plate. The edges of the paper were then folded over and made to adhere to the card frame in front. This was found in practice to be tedious to do, and, if not done very neatly, was liable to check the plates whilst moving round in the camera. After trying several plans, we hit upon one which was so simple that we were only surprised that we had not thought of it sooner, which is to take a strip of gummed paper, and stick in the centre a strip of cardboard the width of the plate; these strips are then folded round the ends of the plate, and secured by being attached to the back of the plates. I think, gentlemen, if you will try to attach some of the strips lying on the table, you will say the plan adopted for the protection of the film is as simple as it is efficient. The plates, of course, are coloured on the back.

In some of the first cameras we made it was frequently asked, "But suppose we purchase our dry plates ready made, and they are of a different thickness to those the cameras are made for, how will they revolve?" This was a question which I could not answer, but felt there was strong ground for objection, and after a little time this difficulty was overcome by as simple a means as the former one. The point to be gained was to have a slot through which the plates passed after exposure, which would increase or decrease according to the thickness of the plate. This has been effected by cutting the bottom of the upper compartment in two, and putting between the two pieces a spring.

The tourist's camera measures five inches by five inches and eight inches high, and weighs, when filled with twenty-one $4\frac{1}{4}$ by $3\frac{1}{4}$ plates, $6\frac{3}{4}$ lbs., which, when slung over the shoulder, is but little inconvenience to the traveller. We have no doubt that by its agency we shall obtain many a picture from positions which with wet-plate apparatus it would be difficult, if not impossible, to take.

I would venture to suggest that such an equipment is just the one thing needful for our army in the field; for, since we have seen of what great service photography has been to the Prussian army in the late war, we ought to take advantage of every means to improve our military photographic staff.

I trust, gentlemen, you will pardon the egotism I may have been guilty of, for I assure you I feel towards my pet camera something like a fond parent who loves the child that has given him most trouble, so I may be led to eulogise its capabilities more than I otherwise ought to do; for, without in the least detracting from the merit due to the originator of the idea, I may, in justice to myself, lay claim to some portion of the credit due to the successfully overcome coming of numerous difficulties in getting that idea worked out to a practical issue.

ON POSITIVE PRINTING.

BY W. L. SUOEMAKER.*

In presenting this paper, I shall only attempt to explain that which has proved of value in practice; and the prints used in illustration were not made for competition, and, therefore, must only be criticised by the tone.

In positive printing on paper, the paper is immersed or floated on a solution containing chloride. After drying, it is floated on, or swabbed with, a solution of nitrate of silver, which, after exposure, to reduce the chloride, is fixed in a solution of hyposulphite of soda. This is the simple base of printing.

The quality of the print depends upon the amount of salt used in forming the chloride of silver. The manner of applying regulates the amount in the paper.

The kind of salt used regulates the colour or strength. The organic substance used in combination with the salt determines the sensitiveness.

Immersing salts more strongly than floating, and floating more than swabbing. Therefore, heavy paper which requires a heavy salting, we immerse; medium, which requires less, we float; thin absorbs quickly, and we swab it.

The chloride of ammonium produces purple or black tones, chloride of barium sepia or brown tones, chloride of sodium blue tones. We prefer the use of chloride of ammonium. Gelatine, arrowroot, albumen, and other organic substances, are used in salting, to give body or strength to the surface, and have different degrees of sensitiveness. Gelatine, with us, has always been found the easiest managed and most sensitive.

Saxe paper requires to be floated longer than Rives', which is more absorbent. This applies both to plain and albumen paper.

I find great difference of opinion existing in regard to the proper strength of silver, and as to the time of floating and fuming.

The time of floating determines the delicacy of the print, and the strength of the silver the strength of the print.

I have found more prints ruined by floating too long than by any other error. Paper floated too long absorbs too much silver, decomposes much quicker, gives less definition in the shadows, injures, and frequently flattens, the appearance of the print. Too short a time produces weak and mottled prints, incapable of receiving a tone.

I have always worked my silver perfectly neutral and perfectly plain, using it, in summer, at 20 grains; in cold weather, from 30 to 40 grains; now working, 35 grains; floating both plain and albumen paper forty-five seconds; fuming ten minutes.

Whenever, in warm weather, my silver solution decomposes, I add a few drops of a strong solution of permanganate of potash; but this will fail to act if the solution has albumen or gelatine in it, and we then remove it by boiling.

Paper should be perfectly dry before fuming; and, if damp after fuming, be dried before printing. The brilliancy of the whites is destroyed by being damp. As fuming increases the sensitiveness of the silver on the surface, the time should be in proportion to the strength of the solution. The treatment of the prints after printing determines the quality of tone. Ten minutes' washing in running water I find sufficient, and will tone more brilliant and with better results than a longer washing, which produces flat results.

A toning bath should never be decidedly alkaline, as it produces measles by dissolving the albumen surface.

Salt is used in the toning bath to precipitate any free nitrate, and prevent meanness.

The kind of alkali used in combination with the gold determines the tone.

For sepia or brown effects, the acetate of soda or citrate of soda baths are generally used.

For blue or purple tones, bicarbonate of soda, borax,

* Read before the Pennsylvania Photographic Association, January 9.

lime, chalk, are used. But it will be seen, by the samples shown, that but little difference can be seen between any, as, by careful manipulation, the same tone can be produced by all. After toning, the prints should be kept wet until fixed.

The strength of the hypo solution determines the time they should be kept in. I use two ounces to the quart, and time twenty minutes to thirty. I prefer placing the prints in the solution face uppermost, dashing the solution over the surface; then reversing and changing several times before removal for final washing.

We always dry our prints spontaneously; and I would here add, for the benefit of all, that prints that dry too blue may be reduced in tone by steeping in boiling water, as will be seen by the sample, on the card, of trial prints.

COLOUR.—TEXTURE OF NEGATIVES.

BY M. CAREY LEA.*

SOME wet negatives exhibit a peculiar cream colour, which occasionally reaches to a faint pinkish tinge. I had often observed this, without even guessing at the reason; but the observation of an extremely great variety of negatives, made in the most different manners, has led to the explanation: the colour in question arises from a certain fineness of the deposited silver.

In working, some years ago, the glycerine and honey process of Mr. Harrison, I noticed the almost excessive fineness of the deposit of which the negative was made up, a fineness that made the negatives suffer more than negatives ordinarily do in the fixing bath. Connected with this fineness of deposit were some curious freaks of colour. For example, if the negative was considerably over-exposed, the sky would come out blood-red. This deep red colour was connected with an extraordinary fineness of deposit, so great as to render that part of the negative quite transparent, so that it looked not unlike the ruby glass used in stained glass windows.

This red colouration by extremely fine particles of a metallic body, ordinarily destitute of that colour, is very curious, and reminds one of the experiment in which gold is reduced to so fine a powder that it remains suspended in water for weeks, imparting to the water a deep red colour.

In the glycerine and honey process red is not the only colour produced, but shades of purple, and even of blue. These shades seem to indicate a still greater degree of fineness of deposit. These seem to show that iodide of silver is capable of assuming a variety of shades of colour just as chloride can.

This influence of the fineness of deposit upon colour may be roughly exhibited in the following manner:—

Let a piece of glass be ground on one of its substances with common sand. Its texture may be taken as a comparison for certain negatives of extremely coarse grain taken under conditions that will be referred to presently. If we use finer sand, we get a finer grain, corresponding to that of another class of negatives. But if, instead of sand, we take fine emery and simply "gray" the glass—that is, just take off its surface—we shall find that if we observe a distant bright object—as a white window-shutter across the street—in direct sunlight, it will show a distinct light orange tint. This property of the glass is much more strikingly shown by closing a window shutter, and allowing a beam of light three or four inches square to fall on a table. On the table a piece of looking-glass—or even a piece of ordinary window glass—is laid, so as to reflect the beam of light upon a white ceiling. If the piece of grayed glass be held in the path of the ray, the spot of light on the ceiling will change from white to orange colour.

The matter has also a certain practical interest in this respect, that these negatives with a creamy shade of colour seem to print particularly well, and to give a beautiful

silky velvety look to the print. Without undertaking to affirm that the finest quality of print can only be got from such negatives, I think I may say that coarser grained negatives are not very apt to produce them.

It is certain that a large proportion of bromides in the collodion is very apt to produce a granular crystalline (very white) deposit on the negative; and, moreover, that such negatives, however fine they may look to the eye, are very apt to be disappointing in the printing. They mostly prove to be thinner than they seemed, and to give a tame and characterless spirit. Some of these negatives will deceive even very experienced printers.

On the other hand, a good cream-coloured negative will often be found to be completely free from all traces of granularity. In some conditions of the bath, the material of which these cream-coloured negatives are built up has a certain clearness about it, so that it, so to speak, looks as if it had been mixed up with varnish. Such negatives are apt to give soft, bright, silky prints.

Of course, other conditions besides excess of bromide in the collodion will give gray granular negatives. Very acid baths, or old baths, tend that way.

I have never tried the plan of putting glycerine into the developer, which was proposed not very long back; but if it should be found to promote fineness of deposit, it would have a real advantage; and the facts that I have mentioned respecting the glycerine and honey bath would seem to render this at least possible.

Correspondence.

ON THE INFLUENCE OF RED LIGHT IN THE CAMERA.

SIR,—Having seen an article in the PHOTOGRAPHIC NEWS ALMANAC, 1871, contributed by M. A. de Constant, on the influence of red or rose-coloured light in the camera, it struck me at the time that it might be made available for a reverse negative process by making a fluid or built-up prism to fit on the lens, filled with rose-coloured fluid.

I have not yet tried it myself, but shall do so on the first opportunity. In the meantime, I give you the idea as it occurred to me, hoping it may be of service to the profession.—
I remain, yours,
ALPHA BETA.

ALBUMINIZING PAPER BOTH SIDES.

SIR,—A correspondent, Mr. Monkhouse, in your last number of the PHOTOGRAPHIC NEWS, gives a recipe for sizing the backs of photographs in order to counteract the porosity of the paper ordinarily used.

The application of any such substance, either on the entire sheet of paper, or on each individual impression, would be simply "a bore," even if successful.

Has any one suggested that the paper should be albuminized on both sides?

I throw out the hint for what it may be worth,—and am, sir, yours obediently,
C. S. HERVE.
15, High Street, Aldershot, March 12th, 1871.

MOONLIGHT PICTURES, ETC.

SIR,—In the last number of the NEWS there appeared a letter from M. Ogier on the above subject, on which, with your permission, I would like to make a few remarks.

In the first of his speculative observations, he sets out by asking, or rather asserting, that "the moon must possess an illuminating power of its own [besides the reflected light of the sun], because its light impresses the sensitive plate the greater the distance from the sun; that its light is more powerful at 11 o'clock than 9," &c. Now it must be apparent to any one who takes the least trouble to enquire, that such is not the case. If it were so, we would always see the moon full, whatever might be its age—at least the part illuminated by the sun could always be seen, which any one who has looked at the moon with the telescope, or even with the naked eye, knows is not the case. That the light would be mere actinic at 11 o'clock

* Philadelphia Photographer.

than 9 may be true enough, because its altitude would then be a good deal higher.

With regard to the relative light of the sun and moon, he is likewise in error. He says: "Moreover, the moon ought to produce the photographic image in a proportionate space of time to the sun—that is to say, 2,000 or 10,000 times more slowly. But this is not the case; for, while the impression is produced in a quarter of a second in sunshine, with the same apparatus and a similarly prepared plate, twenty minutes suffice to secure the so-called lunar reflection, instead of exactly 666 hours or 23 days, which would be necessary if, as it is affirmed, the sun's rays are actually 10,000 times more intense than those of the moon." Now if the sun produce a certain effect in a quarter of a second, and the moon the same effect in twenty minutes, he would have given the picture of the moon 4,800 the exposure than that of the sun picture; and an exposure of forty minutes would give 9,600 that of the sun, which would be pretty near the 10,000 times he speaks of.

The relative actinic light of the sun and moon have never, I believe, been correctly estimated. The "Old Photographer," in his "Echees," when M. Ogier's pictures first appeared, estimated (on whose authority I know not) the moon's light as 30,000 times less than that of the sun, and M. Ogier speaks of some one giving 10,000 as the figure. Now I think that neither of the above figures are correct. From some experiments of my own, I conclude that the actinic light of the full moon is from 5,000 to 7,000 times less than the sun. I have taken pictures of the full moon which were properly exposed in from four to seven seconds. They were taken at the focus of a telescope $4\frac{1}{2}$ in. in aperture, 6 feet in total length. With the same instrument I calculate that a picture of the sun would be properly exposed in about the 950th to 1000th part of a second, which would give about 5,000 to 7,000 times as their relative intensity.

Further on he says, "The fixed stars and planets have also a considerable illuminating power, which may be added to that of the moon." Now, whatever actinic power the stars and planets may possess in themselves, they can have little or no effect on a landscape as far as photographing is concerned.

With regard to starlight in Sweden and other high latitudes, I may say that it is not simply starlight, but rather sunlight. In the island of Lewis, in the north of Scotland (which is in the same latitude as Sweden), there is a hill on the top of which for one or two days in the year the sun never sets, and for two or three weeks at that time of the year it would be possible to take a picture the whole night through, simply by the reflected light of the sun, so little is it below the horizon.

To conclude, I believe it perfectly possible that a picture may be taken by moonlight; indeed, if I mistake not, I have seen it stated years ago that Mr. Breeze had taken a white statue by moonlight, with an exposure of half an hour. It was not till lately that I had the pleasure of seeing Mr. Robinsen's picture "The First Hour of Night." That it is a splendid picture there can be no doubt; there likewise can be no doubt that it was not taken by moonlight. It is perfectly apparent to me that the sea and sky were not taken at the same time, but separately. The sea, in my opinion, is taken in full sunlight, and instantaneously; and the sky and moon at another and suitable time, with an exposure of a few seconds. In fact, were it not to considerably lengthen my letter, I might prove from the picture itself that the sea and sky were not taken looking to the same point of the compass; and with a little trouble in calculation, I could tell the year, day of the month, and hour of night on which the picture of the moon was taken, and likewise the focal length of the lens with which it was taken.

Apologizing for the space I have taken up, believe me yours, &c., J. M. TURNBULL.

Edinburgh. March 14th, 1871.

PHOTOGRAPHS OF THE LATE ECLIPSE.

MY DEAR SIR,—I shall be glad if you will correct an error which appears in the News of last week.

Dr. Vogel was not applied to at the last moment. He accompanied the expedition at his own request, and paid his own expenses. When I heard of his wish to be attached to my party, I wanted to know something about him, and applied to you for information, and in your reply you gave me his address. I did not ask you for it. Dr. Vogel was at Etna, I was at Syracuse. I do not wish it to be supposed that I owe my

success to Dr. Vogel, as anyone reading your remarks might suppose.

It is much to be regretted that bad weather prevented Dr. Vogel getting any pictures of the corona.

Enclosed is a copy of my No. 5 picture, also a copy of the American.—Yours very truly,
A. BROTHERS.

Manchester, March 14th, 1871.

[Our correspondent will note that we stated that Dr. Vogel was with the Etna party, and, as we have before published his graphic account of his operations, and the bad weather which caused his failure, our readers could not suppose we attributed Mr. Brothers' success to him. Our correspondent's memory is in error. His enquiry extended, amongst other things, to Dr. Vogel's whereabouts. Thanks for the admirable photographs.—Ed.]

REDUCING A NEGATIVE BATH TO CARBONATE OF SILVER TO PURIFY IT.

DEAR SIR,—Having successfully tried the method of treating worn out negative baths described by Mr. Brooks in the YEAR-BOOK, possibly an account of my mode of procedure may be of use to some of your readers.

Perhaps it would be as well to state that the bath I experimented with had resisted nearly all the known methods of doctoring, and was given up as only being fit for residues. I first diluted the bath to about three times its bulk with distilled water, and sunned till the milky deposit had settled to the bottom; and after filtering, added solution of carbonate of soda until a slight turbidity was produced, sunned for about half-a-dozen hours, and again filtered. I then added carbonate of soda until the whole of the silver was thrown down as a carbonate, decanted the solution, and washed the precipitate in four or five changes of water, using distilled water for the last washing, and, after decanting as much of the last washing water as I possibly could, I proceeded to dissolve the carbonate, which I found rather difficult. I used an aqueous solution of pure nitric acid, consisting of three parts acid to eight of water, and of which I added (cautiously stirring all the while) about half an ounce. I then left it for two or three hours, and again added the acid. This I repeated several times, until the precipitate was nearly all dissolved. The solution then was inky black, and I must say I thought the experiment a failure.

I nevertheless thoroughly filtered it, and made up in bulk to about 35 grains to the ounce. Believing that, although I could not dissolve the whole of the precipitate, my bath was a very great deal too acid, I tested it, and found I was right in my conjecture, and after neutralizing and sunning for about a week, I ventured to try a plate, and was agreeably surprised to find my bath in splendid condition, and gave negatives free from stains, fog, or pinholes, and that, although attended with some slight mishaps, my experiment was, in the end, a complete success.

Not knowing the exact conditions under which "A. W. H." worked, I cannot venture to offer an opinion as to the cause of the purple crystals formed in his bath. In my own experience, once, on the application of the developer to the plate (while experimenting) a thick purple veil or fog developed out, and entirely enveloped the picture. That I accounted for through having added an excess of ammonia, and afterwards removed by adding nitric acid.

I have also noticed that one of my baths, while sunning, turned slightly purple, and in that state gave very foggy negatives, although quite free from pinholes or comets, and which purple colour would not filter out. In this case I added kaolin, sunned, and filtered, and was pleased to find I had removed the purple colour from my bath, and could produce negatives entirely free from fog.

Hoping the above will be of some slight use to "A. W. H.," I remain, dear sir, yours truly

A YOUNG PHOTO STUDENT.

CARBONATE OF SILVER—ALUM IN BATH.

SIR,—I have used the process for reducing a silver bath by means of carbonate of soda for six years, and never met with failure once.

What does "A.W.H." mean by 80 grains* of bath? Does he mean 80 grains of silver to the ounce, or 80 ounces of bath? If the former, I think that the solution, being too strong, might

* Ounces were doubtless meant.—Ed.

have a tendency to precipitate, and cause spots upon the film. But I cannot think what is the cause of the purple crystals, unless the bath originally contained acetic acid, and had permanganate of potash in it as well. I expect that the two combined might cause purple needle-shaped crystals.

On dit. If Mr. Wyles, in addition to ammonia, will add alum to his nitrate bath, he may dispense with both washing and fuming his paper, and the strength of the silver will not need to be greater than 30 grains, and the paper will keep white longer than in the washed process.—I remain, yours truly,

March 14th.

W. T. WILKINSON.

Proceedings of Societies.

THE PENNSYLVANIA PHOTOGRAPHIC ASSOCIATION.

The meeting of the Association was held on Monday evening, January 9th, 1871, Mr. ALBERT MOORE, Vice-President, presiding. After some routine business,

The paper for the evening was read by Mr. W. L. SHOEMAKER, assistant to Mr. Moore, the solar printer, "On Positive Printing" (see p. 127.) Mr. Shoemaker illustrated his paper by a number of prints of one subject from the same negative, printed and toned by fourteen different photographers by as many different methods. His paper was greeted with applause, and followed by a discussion on the different methods of printing, and the advantages of heat in changing the tone of prints on paper and on porcelain.

Mr. SAYLOR said it was his habit, in porcelain printing, to dry the plates spontaneously when he desired a warm sepia tone, and if they were a foxy red, he could improve them by drying by heat.

Mr. SCHREIBER said if cyanide was used for fixing, the print and the tone of the porcelain could both be regulated and reduced.

A negative was shown with the film badly split up and partly dissolved away, the party claiming that it was caused by the varnish. Several guesses were made as to the cause, as it seemed an unusual effect, and among others the following: 1. Dirty plate, and old, thin collodion. 2. Intensified with bichloride of mercury, and varnished with a varnish containing ammonia. 3. More alcohol in the collodion than in the varnish. 4. Imperfect fixing and washing. 5. Under-timed, improperly washed, and film eaten away by bichloride of mercury. 6. Rotten collodion, and dirty plate. No one seemed to think the varnish did the mischief, and a vote was taken on the subject, and it was decided that the varnish could not have caused the breaking up of the film.

Mr. CLEMONS then stated that the varnish used was his new N. P. A. varnish, and he was glad to find it innocent, as he knew it was. In answer to the second guess, he stated that there was no ammonia in his varnish, and it would dry without heat in a room of 60° temperature.

The SECRETARY, Mr. R. J. Chute, then read his annual report.

Dr. Vogel was then elected the first honorary member of the Society, the vote being taken standing.

Mr. WILSON stated that there was another gentleman, a warm friend of America and American photography, whom he desired to propose for honorary membership, Mr. G. Wharton Simpson. His proposition was heartily received, and Mr. Simpson unanimously elected.

It was resolved that the protest of this Society be filed with the Commissioner of Patents, against the extension of the patent for solar cameras, granted to D. A. Woodward, Feb. 24, 1857, and the Secretary was instructed accordingly.

The proceedings terminated by the exhibition of various interesting matters.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of this Society was held in the City of London College on the evening of Thursday, March 9th, the Rev. F. F. STATHAM in the chair.

The minutes of a former meeting having been read and confirmed, Mr. B. J. Edwards and Mr. W. Brooks were elected members of the Society.

Mr. C. E. ELLIOTT then read a paper on Cook's Camera for Dry Plates (see p. 126), and illustrated it by exhibiting the instrument itself, showing the admirably perfect way in which,

after exposing a plate, it was passed into a reserve cell, and a fresh plate brought into position before the lens by this simple and unfailling machinery, provided as described in the paper.

Mr. J. T. TAYLOR, answering a question as to the risk of the opaque backing of the plate being removed by the pressure of the spring against which the plate had to slide, said that he had met that difficulty very easily. He coated the backs of the plates with Spanish brown and gum-water, and then gummued a strip of paper across the middle, against which the spring pressed. This removed all risk of the colour rubbing off.

A desultory conversation followed, on the possibility of removing one set of plates in the field, and placing another set in position, without risk, which, with a little care, it was shown might be easily done. After some further conversation,

Mr. TAYLOR said he thought it ought to be known that the present perfection of the apparatus was chiefly due to Mr. Elliott, who had done as much in improving it as the patentee in first inventing it.

Mr. B. J. EDWARDS said that everyone must admire the exceedingly ingenious camera and its convenient arrangements. So far as dry plates were concerned, nothing could surpass it; but he must confess to a prejudice against the use of dry plates, and the trouble, risk, long exposure, and uncertainty involved in their use. He thought that no photographer would willingly use a dry process when wet plates were available, and he was happy to announce that, having spent much time in trying to combine the advantages of the two, he believed he had succeeded. Without entering into detail, he might say that he hoped shortly to be able to describe a means of taking wet plates without tent or dark room, with apparatus less bulky or heavy than was required for dry plates.

Mr. FRANK HOWARD, recognizing the ingenuity of the camera which had been exhibited, must confess that he thought nothing would supersede double backs for convenience and simplicity.

After some further conversation and a vote of thanks,

Mr. PRICE exhibited his metal camera and some negatives which had been produced in his last year's tour. They were produced on collodio-albumen plates, with a final wash of gallic acid. They had been prepared in May, and some of them not developed until November or December; all yielding good negatives except a few which had been subjected to great heat whilst in the backs, and these fogged. He used three lenses for the same sized plates to suit the different classes of views he wished to take. The plates were the ordinary quarter-plate, and the lenses were of 2½ inches, 5 inches, and 9 inches focus respectively. Each was focussed, previous to going out, for a marked place in the camera, and for subjects at a distance suited to each lens, required no further focussing, all objects beyond the proper distance being in perfect focus. For near views, of course, the lens of short focus was used, whilst for distant scenery a lens of long focus was indispensable. The framework of his camera was light and portable, and worked easily and accurately. The general design was like the Kinnear camera, the framework being metal. He used three double backs, and generally found that six plates were the utmost he could expose with advantage in one day. He showed also a little camera he had designed some years ago, but never carried out. It was intended for use with curved mica plates, and had combined with it a series of baths, so that the plates could be prepared and developed in the field without a tent.

A general conversation followed, in the course of which much admiration was expressed for Mr. Price's metal camera, which, for compactness, efficiency, multiplicity of ingenious details, and accurate workmanship, we have rarely seen equalled. After a vote of thanks,

Mr. BARNES exhibited an interesting series of the early collodion negatives of the late Mr. Archer, originator of the collodion process. He also showed a book in which had been placed a number of these negatives transferred by means of gutta-percha, as patented by Mr. Archer. These had all decomposed, and now consisted simply of broken fragments. After some conversation, and a vote of thanks to Mr. Barnes,

It was announced that at the next meeting Mr. B. J. Edwards would exhibit his new apparatus for working the wet process without a dark room, and that Mr. Foxlee would read a paper on the quality of small negatives best suited for enlargements.

The proceedings then terminated.

PHOTOGRAPHIC SOCIETY OF LONDON.

The usual monthly meeting of the Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, the 14th instant, Dr. MANN in the chair.

The minutes of a previous meeting having been read and confirmed, Captain Stanley Mortimer and Mr. John Sherrington were duly elected members of the Society.

Mr. REJLANDER then introduced the subject announced for the evening's discussion: the cracking of negatives, of which cracking he proceeded to say there were two distinct kinds, which he wished to distinguish as *cracking* and *splitting*. In the first, the film was raised in irregular ridges, which were due, doubtless, to damp. The second form was a very fine distinct splitting in the film, and his object was to ask the collective wisdom of the Society if a cause or cure could be assigned to the latter form. Two reasons were given by crack makers for this splitting. One was imperfect washing after fixing the negative; and the other, that the film had not been quite dry when the varnish was applied. This he did not believe, as in some cases, when he had seen a tendency to a film splitting in drying, he had hastily applied varnish before the film was quite dry, to save it, and these had not cracked. He might mention one bit of experience, that he never had this splitting in small negatives, only in large ones, and the splits were generally in the shadows. The question he should like answered was this: Was the fault due to the varnish, or to the collodion? The chief examples which he had had belonged to one year's productions, those of 1861. He produced two negatives produced some fifteen years ago, under the same circumstances, and treated alike, both being treated with Archer's gutta-percha varnish. One had split, and the other had not. A manufacturer of varnishes, not photographic, recently told him that varnish cracking was generally due to the condition of their under-coating; if that were good, the varnish would never crack; and instanced the case of a painting upon a joined canvas: one portion cracked all over, whilst that on the other piece of canvas remained quite good. His aim was to show examples, which he now did, and to ask for information.

A variety of curious examples of cracking and splitting, both in negatives and transparencies, were then handed round for inspection.

The SECRETARY then read a communication from Mr. England on the subject, in which he expressed a conviction that the collodion was often in fault. The action of the nitrate of silver, derived from the albuminized paper attracting moisture, might also operate; and he recommended that the negatives, after printing, should always be cleaned, and then treated with a paste of wax and turpentine. When these fine splits had occurred, he found that Indian ink and water, rubbed in with a piece of silk, was more effective than black-lead or lamp-black in powder, and lasted much longer, permitting hundreds of impressions. He showed an example in the form of a print from a split negative, before and after treatment with Indian ink: the first being covered with black lines, the other not showing any trace of them.

Mr. REJLANDER said that the remedy, filling up the cracks in the shadows as much as the lights, must cause white lines, requiring touching-out in the print.

Several members stated that in practice this did not occur.

Mr. WHARTON SIMPSON pointed out that as the fissures in the film were of different depths, according to the thickness of the deposit in the split part, and the pigment applied only filled the fissure, it followed, that the amount applied followed the gradations of thickness in the negative, and so produced no perceptible difference in printing.

Mr. REJLANDER said the specimen admitted that the fact was there, but he did not still see how it could be.

Mr. HUGHES explained, and some conversation followed, Mr. Rejlander dissenting.

The SECRETARY read a letter from Mr. W. J. A. Grant, and one from Mr. Blair, giving some experiences and opinions on the subject.

Mr. HUGHES said it was important, in a discussion like this, to keep distinctions clearly before them. There were two kinds of cracks, and he thought they would be more clearly defined if they spoke of them as the cracks caused by contraction, which split the film, leaving fine transparent lines; and cracks caused by expansion, which caused the film to rise in ridges, the latter not necessarily showing in printing, but being constantly dangerous, as, when they broke, the defect

could not be remedied. The latter were clearly due to damp. The cause of the other was yet to be determined.

A conversation here arose on the film splitting in drying, Mr. HUGHES suggesting that, as this was in no way connected with the splitting of varnished negatives, it was rather complicating the matter to enter upon that question.

Mr. FRANK GOODE said that, having recently changed his residence, he had had opportunity of proving that damp was the cause of the ridge-like cracks, negatives which had remained good for seven or eight years having suddenly been destroyed by a change to a damp residence. He found the best plan to avoid it was to keep the negatives in paper in open racks instead of in closed boxes. That, in his case, had stopped the evil. The fine, hair-like cracking, he thought, was often due to the use of a large quantity of bromide in collodion.

Mr. ENGLAND used a large quantity of bromide, but he had done that always; and it was only recently he had been troubled with cracks.

Mr. BLANCHARD said there were probably various causes in operation. The fine transparent cracks were due, he thought, to the use of a special kind of collodion, which many of them would recognize by the description. It readily set on the plate, giving a glossy, horny film; was generally very sensitive, and the finished negative pulled away from the edge of the glass. This process, he believed, went on slowly and subtly after the negative was varnished; and eventually, when the contracting tendency met with sufficient resistance, cracked. Sudden changes of temperature would especially tend to this end. The plan of keeping the negatives wrapped in paper was, he believed, beneficial. Imperfect washing away of hypo was a well-marked cause of an especial kind of splitting. He thought negatives kept in the pressure-frames, being protected from the sudden effect of changes of temperature, were safe.

Mr. GOODE, on the contrary, had found many of his commenced their cracking career in the pressure-frame.

Mr. PETER LE NEVE FOSTER asked if any experiment had been tried with films of varnish alone, to see if they cracked.

Mr. ENGLAND said that imperfect washing, so often suggested as a cause, certainly was not so in his case, as he washed the negatives himself, and was most careful.

Mr. GOODE said he could bear similar testimony.

Mr. HUGHES said the subject was too complex to be solved by any general statement. The ridges, he thought, were, beyond question, due to damp. There was the special crack which he knew well as described by Mr. Blanchard, which was due to hypo. He had no doubt that sudden change of conditions was a cause of cracking, and the more carefully negatives had been preserved prior to such change, the more likely they would be to suffer. He remembered a case, which Mr. Blanchard also knew of, in which a box of negatives in good condition having stood by the stove during the day, and being then left in the glass-room during a cold night, all were covered with the ridge-like cracks. Mr. Goode's case was a similar illustration.

Mr. GOODE said he found that negatives on green glass escaped, whilst those on white glass suffered.

Mr. HUGHES had escaped the evil since he abolished plate-boxes, and kept the negatives in envelopes in open racks.

Mr. HENDERSON kept his negatives in parcels of paper, and had none cracked.

Mr. ENGLAND never found a film split which had been re-varnished. He thought it was a good time to clean off the stained varnish, and varnish again.

Mr. SPILLER referred to a paper he read before the Society in 1863, describing a method of curing the ridge-like cracks, by submitting the negative to the vapour of alcohol. He then referred to the practice of various distinguished photographers in keeping the negatives in a dry warm room, out of contact with outer walls; and also mentioned the conclusions of the recent varnish committee at Berlin.

The CHAIRMAN said he had kept negatives in various conditions of temperature, from 29° to 97°, and they had had little washing and much washing without any cracking, except in one series, which in that case was clearly due to the quality of the collodion, as all produced with the collodion of one maker at the time cracked, and these only.

The CHAIRMAN called attention to some interesting instantaneous photographs taken some years ago by Mr. Kibble on collodio-albumen plates, and brought out by many hours' development.

Mr. ROGERSON showed a couple of large copying cameras with many novel and useful features.

Mr. BEASLEY showed some fine views of Gibraltar taken on Fothergill plates.

The hour being late, Mr. Dunmore's paper was postponed, and, after an announcement that Mr. Hughes would read his experiences in carbon printing at the next meeting, and some votes of thanks, the proceedings terminated.

Talk in the Studio.

SOIREE AT THE ROYAL SOCIETY.—The annual soiree of the Royal Society was held on Saturday evening last at Burlington House. The rooms of the Society were well filled with an illustrious company, who were personally received by the President, General Sir E. Sabine, K.C.B., and the principal officers. Several matters of unusual interest to photographers were displayed in the rooms, the principal being, without doubt, the photo-collographic process of Mr. Edwards. In this case the whole process of printing was clearly demonstrated, the operations of inking and pulling the prints being shown large numbers of specimens proved the degree to which the method could be made use of, as also the uniform quality of the prints produced. In another room were exhibited the photographic proofs of the eclipse secured by Lord Lindsay's party in Spain, the pictures being upon glass, and carefully illuminated from behind, so as to convey to the spectator as nearly as possible the effect as seen actually at the period of totality. One of these, carefully coloured to show the true character of the protuberances and corona, and exhibited also as a transparency, proved a very effective picture. Mr. Brown's large equatorial telescope, fitted with photographic apparatus, by means of which the pictures were produced, was also shown, and attracted numerous visitors. Photographs from the General Photographic Establishment at Woolwich, and from the Department at Chatham, were shown, as also some very striking portraits of Sir R. Murchison and the late Professor Miller, together with other prints of merit. Mr. Huggin's spectroscope, Dr. Norris's physiological demonstration, and Mr. Cromwell Varley's electric experiments, were much appreciated, as were likewise other matters of a less ambitious nature, the reunion being altogether very interesting and agreeable.

PHOTOGRAPHY AT THE FORTHCOMING INTERNATIONAL EXHIBITION.—The committee appointed to select the photographs for the forthcoming exhibition, consisting of Dr. Diamond, Col. Stuart Wortley, and Mr. Richard Thompson, met a few days ago to examine the contributions sent in. About sixty photographers had sent collections of pictures for exhibition, comprising a very fine display of photographs. The limited space devoted to photography compelled the exercise of a somewhat rigid selection, space being available for not more than half the pictures sent in. The general plan adopted was to select about half of the examples of each exhibitor, the best pictures being, as far as possible, retained. It is doubtful, however, whether the space available will permit the hanging of all the pictures selected. The position chosen for photographs possesses the charm of loftiness, being within the dome, and just over the music gallery.

To Correspondents.

SOUTH DEVON.—As a rule, a somewhat stronger bath is necessary for dry-plate work than for wet. For most dry processes a 40-grain bath is desirable, and for most processes that strength is sufficient. It depends somewhat on circumstances, however. If you use a very highly bronzed collodion, a stronger bath than that may be used with advantage. 2. The object of flooding dry plates with alcohol and water previous to applying water, is to permeate as speedily and perfectly as possible the horny and repellent film. When once a collodion film has been perfectly desiccated, it is very difficult to render it again permeable by water, which is apt to run over its surface without penetrating, and alcohol overcomes this repellent condition much more readily than water.

E. P. (Chester).—Much depends on varying circumstances. As a general rule, however, six cubic feet of each gas, suppose coal gas be used for the hydrogen, will serve for two hours. In all cases the lime cylinder should be turned round from time to time.

E. S. B.—Some samples of paper have a tendency to lose tone in the fixing bath. The best remedy is to tone somewhat deeper than usual, and to use the fixing bath as weak as may be compatible with perfect fixation.

L. C.—An ordinary photographic dish is not suited for boiling a silver solution. A vessel made of earthenware which will stand fire is necessary; one of the ordinary evaporating dishes used by chemists will answer. You can obtain it of any dealer in philosophical apparatus. You may boil over a fire or over a gas flame. 2. A sand bath is a vessel containing sand which is placed on the fire, and a vessel containing the substance to be heated placed amid the sand. The object is to obtain a steady heat free from flame or varying conditions.

YOUNG PHOTOGRAPHER.—The shade around the figure in a vignette is the natural tint of the background against which the figure was taken, which is graduated into white margin by means of vignette glasses, or other means of vignette masking. You will find instructions for producing vignettes in most manuals of instruction.

A PRINTER.—There is no regular rule prevails as to the working hours of photographers, nor as to the time at which they leave off on Saturdays. In some establishments we know that business ceases at two o'clock on Saturdays; in others, continues until evening on that as on other days. The justness or desirability of employers giving a weekly half-holiday to their work-people is a wide one, and involves many considerations. We at all times counsel a liberal and kindly policy amongst employers. We can quite conceive that when a good understanding exists between employers and employed, the latter, by extra energy, care, and effort on other occasions, may compensate employers for giving the half-holiday. On the other hand, assume that the bargain between the parties of so much wages for so many hours of work is a just one, then to ask permission to curtail the number of hours without reducing the wages is equivalent to asking for a gift of so much money. It should further be remembered that even if a half-holiday be granted, Saturday is, for many reasons, not the most convenient time. The fact that city houses and other business establishments close early on that day gives the attendants in such houses leisure to sit for portraits, and hence it is often the very time when the photographer feels the imperative duty of remaining open to oblige customers. Photographers have so much enforced idleness during bad weather, that many of them cannot afford holidays when the sun shines.

F. P.—There are many very effectual methods of cleaning glass plates, and also several effective methods of dispensing with very careful cleaning. Much depends on the condition of the plate to begin with. New glass we should clean simply with alcohol and rotten-stone, or whiting, applied with a tuft of cotton-wool, and rubbed off with a perfectly clean linen. For old plates nitric acid, or strong cyanide, made into a thin paste with whiting, answers well. There are many other methods; but these we have most commonly used. The preliminary coating with dilute albumen, or tunicare, also answers well, and renders care in cleaning the plate of less importance. 2. Gold from old toning baths is easily recovered. The method by the addition of sulphate of iron, which we have often described, is very easily applied. Pyrogallie acid also answers well. Making the solution alkaline, and boiling in a Florence flask, will reduce the gold.

H. BRILL.—Much depends on the kind of experience you have had. The coffee process is, perhaps, the most simple process for keeping a few weeks. The Fothergill process is similar in simplicity and keeping qualities. The gum-gallie process is better where longer keeping qualities are desired. 2. There is no photographic journal issued in Canada.

WILLIE JACKSON.—You need not register an enlargement from a negative to protect, if the proper steps have been taken with the original photograph. 2. You cannot legally copy a copyright picture without the consent of the owner of the copyright, no matter who may desire you. You had better get the gentleman to sit to you direct. 3. You cannot legally copy, in large size or small, a copyright engraving. 4. Glue for mounting prints is the same as that used by joiners, but of the best quality. The material applied to the back of postage stamps is dextrine. 5. There is a fair demand for photographic portraiture at present, but not quite so much as during what was termed the card mania about half-a-dozen years ago.

A. K. K.—There are two methods of fuming: one consists in placing a little ammonia in a saucer at the bottom of an air-tight box, pinning a piece of sensitive paper to the lid, and closing the box for ten minutes; another consists in fuming the pads, which are placed at the back of the paper in the pressure-frame. In this case, the pads are kept previously shut up in a box, with either liquid ammonia or carbonate of ammonia. 2. The paper should be quite dry before fuming. 3. The advantage is, that with weak baths, and little or no free nitrate on the paper, rich vigorous prints are obtained. 4. A porcelain evaporating-dish, made for the purpose, placed over a suitable gas jet, or a clean, hot fire, is best for boiling down a bath.

H. TILLY.—The proportions are generally pretty good, but we should prefer the width 12 feet instead of 10 feet, and the height at ridge 14 feet instead of 13 feet. The glass north side and roof will do well. As direct sunlight is better kept out of the dark room, even through yellow glass, a north window is best.

C. R. W.—Thanks.

M. DE CONSTANT ON DRY PROCESSES.

WE commence, in the present number, a series of papers on dry-plate photography by Mons. A. de Constant, especially in relation to the gum-coffee process, which he has worked out with so much care and success. The remarks and instructions of M. de Constant possess the especial value of being the dicta not only of an ingenious and indefatigable experimentalist, but of a skilful practical worker of very fine taste. It has, unfortunately, happened occasionally, in connection with dry-plate photography, that those who have experimented and written the most have practically effected the least; and when, by chance, their work has been seen, it has been found of a very low standard indeed. Some of the ablest dry-plate workers have, on the other hand, had but little to say in relation to their operations. It is a fortunate conjunction, therefore, to find the indefatigable experimentalist, the skilful worker, and the able writer united in one person. M. de Constant has, for years past, experimented carefully with all the dry processes; and, after mature experience, has come to the conclusion that his combination of coffee and gum unites the largest number of desirable qualities: simplicity, certainty, rapidity, and excellence of result. We have been favoured, from time to time, with many examples of its results, possessing most admirable qualities, some instantaneous street scenes before us equalling the majority of similar subjects we have seen produced by means of wet collodion.

In simplicity, this process leaves little to be desired: a plate is coated, excited, washed, coated with the preservative, and dried. It is then ready for exposure, and will keep a few weeks. The exposure, as estimated by M. de Constant, is about three times that of wet collodion. In saying this, it should be understood that the author gives a thorough exposure, securing detail, softness, and harmony throughout, and not simply the hard, black-and-white pictures too often produced on dry plates; and, judging from the examples before us—for, except experimentally, we have not worked the process to any great extent ourselves—the especial tendency of the method in question is to produce thoroughly harmonious pictures.

In reading M. de Constant's experiences with this process, it is curious to note how nearly they coincide with those of one of the earliest and most successful dry-plate experimentalists, Dr. Hill Norris. The use of a powdery collodion, the necessity of retaining a porous, permeable condition of film, are conditions in the operations of both gentlemen; and there is a close resemblance in the substances employed as preservatives, Dr. Norris having used tannin and gelatine, and M. de Constant coffee and gum. The use of the coffee and gum preservative seems to satisfy, as does the use of its congener gallie acid and gum, two

cardinal conditions of success in dry-plate photography, and meets the chemical and mechanical necessities of the ease. Dr. Vogel, as our readers remember, discovered, a few years ago, that the necessary condition to render iodide of silver sensitive to light was the presence of some body having an affinity for iodine, with which it might combine when separated from the silver. Hence free nitrate of silver was necessary in the wet process, and some body which might perform a similar office in the dry processes. Gallie acid, tannic acid, caffeine, and similar bodies possess such an affinity, and absorb the iodine liberated by the decomposition of the iodide of silver; and these substances preserve the best chemical conditions, whilst the mechanical condition of ready permeability is secured by the use of the gum and sugar added to the solution.

Besides containing fully detailed particulars of all the operations, with comments on their *rationale*, some important points of novelty will be found in M. de Constant's papers, especially in relation to development, to which point he attaches considerable importance. Commencing with alkaline development, he has found that it may be supplemented with great advantage by means of an iron solution, which, in case of short exposure, is invaluable in forcing development. For details of this, and other parts of the process, we must refer the reader to the articles themselves, as our aim is not to epitomise, but to call attention to them, and to the repeated evidence we have had of the excellence of the process, in the charming specimens we have received from time to time, including almost every class of subjects, from instantaneous pictures to reproductions.

GRADUATED BACKGROUNDS.

The value of a graduated tint on the background of a portrait is well known to most photographers. It is not only a valuable adjunct in securing pictorial effect, but it materially adds to the relief and force of the picture, removing the flat inlaid effect which is too common in portraits with a background of one even, unvarying tint. Various modes have been devised of producing this effect, such as painting a graduated tint on the background screen, varying the light and shadow on the screen, moving or revolving the screen, and other methods. We have recently received from our friend Mr. E. L. Wilson an example of the result of another mode of securing this effect, devised by Mr. R. Benecke, of St. Louis. It consists in employing a triangular frame, covered with white or grey paper, to move over the background during the sitting. The background used is a dark one, and the light-coloured triangular screen being kept in motion in front of the part where a lighter tint is required, the effect is produced without any

definite line or edge being produced. The triangular screen must, of course, be furnished with a handle—for convenience, a somewhat long one—and its use entrusted to a second attendant. The light may thus be introduced in any portion of the background where it may be required to produce the desired relief. A screen of dark or black velvet might, in a similar manner, be used to introduce dark tints into the picture, where it may be needed for the purpose of chiaroscuro.

VIGNETTE PORTRAITS: HOW TO LIGHT AND HOW TO PRINT THEM.

BY GEORGE CROUGHTON.

ALTHOUGH the vignette is one of the most pleasing of the many styles of photographic portraiture, and one that is now becoming very popular, I think the consideration of their improvement artistically has almost entirely been overlooked by photographers generally.

It seems to me that the advent of Mons. Salomon's pictures, while stimulating photographers to improve their full and three-quarter portraits, has caused the vignette to be left out in the cold. I know there are many who think that a vignette portrait is the easiest thing in the world to produce, for I have more than once heard it remarked that they would much rather take a vignette, because it was no trouble: there was no posing, or arrangement of accessories wanted. This is true to a certain extent, but there are other things that require thought and taste in almost as great a degree as a full-length. There must be quite as careful a study of the lighting, as in a full-length portrait, and although a bad pose may not be so conspicuous, a graceful and easy pose is one of the chief charms of a good vignette. Then the vignetting in the printing requires great taste and judgment, for it is quite easy for the printer to spoil efforts aimed at by the operator. To a man that uses the so-called vignetting glasses, it may seem an easy thing enough to vignette a portrait; but I contend that such are not vignettes, they are simply ovals, not sharp at the edges. I think there is nothing so abominable in the eyes of an artist as the regular oval these glasses produce.

A vignette head should be lighted in such a way that there should be no strong contrasts of light and shade; the whole should be soft and round, and, at the same time, it should not lack brilliancy, but the whole should be less solid than would be required if it had a dark background behind it.

I have noticed, in the productions of photographers who have aimed at softness, a tendency to flatness and loss of brilliancy; while, on the other hand, the man that aims at brilliancy has a tendency to hardness and strong contrasts. I think this is entirely due to a mistaken idea about the exposure. In both cases, if the photographer aiming at softness gets a soft light upon his model, and gives a full exposure, there must be loss of brilliancy; if, on the other hand, the one aiming at brilliancy lights his model boldly, and does not give a full exposure, he must lose softness. Now, my idea is, that if a head is lighted so that it has a good bold round shadow, with not too dominant a side-light, and a full exposure be given, both softness and brilliancy will be the result. For a vignette, in my opinion, the light should be more evenly distributed, and very strong shadows should be avoided; they should be altogether lighter, softer, and more ethereal (if I may so use the word). Then, again, they should not be too large for the paper they are on. I am led to say this because it has become the fashion to put heads upon cartes that ought rightly to be on 10-8 paper. This is preposterous; you never see artists spoil a head by putting it on too small a paper; on the contrary, they sometimes go to the opposite extreme; but it is far better to see a small head on a large paper than *vice versa*. A one inch head is quite large enough for a carte vignette.

But it is in the background that the chief improvement would be made. The proper distribution of light and shade upon the background of a vignette is its chief charm. It is one of the greatest difficulties an artist has to contend with in the production of a vignette portrait, particularly if it is done in chalk; but the difficulty to the photographer is not nearly so great, for, in the case of the artist, the effect mainly depends upon the freedom of touch and masterly handling of his chalk, the knowing what to do, and how to do it at once, for there must be no supplementary touches; but, on the part of the photographer, it only requires him to know what to do, and the various means of doing it will only require the exercise of ordinary judgment and taste to suggest themselves. On no account should a dark background be used, nor should it be too light; it should be dark enough to relieve the lighted side of the face, and light enough for the shaded side to come forward from it, but it should not be of an even tint—that is, the same one side as the other. I will explain the principle upon which the light and shade upon the background is based, and the application will suggest itself.

We will suppose a head placed before a background of a medium tint, lighted by one direct ray of light, as from a window in an artist's studio; the background would receive that light obliquely. The light that falls upon the face does not reach the background on the side the light comes from, therefore the lighted side of the face is relieved by the shaded part of the background; but, passing behind the head, it lights the background on the shaded side of the head, at once throwing the whole head forward. But left as it is, the picture wants balance; it is all shade one side, and all light the other; but letting the light finish its work, we see the shadow of the head thrown upon the background, just by the shoulders, which gives the balance wanted; so by merely acting upon these principles of light and shade, we have what is wanted, the head relieved, and coming forward from the background, and the background itself playing the most important part in that effect.

I will close this paper with a few words upon the methods to be used for the production of this effect in photographic portraiture. One of the simplest is the use of a card with a proper-shaded opening, and the use of cotton-wool. Another and better method was described by Mr. V. Blanchard at the South London Society some time ago; it consists in the use of flake white on the glass side of the negative, and worked with the fingers into a regular grain in the shape required. But decidedly the best way would be to have a background painted on purpose on a light grey ground, with a little hatching of a darker colour where the cast shadow should fall.

If these few remarks should have the effect of calling the attention of photographers to a style of picture which will pay for trouble spent on its improvement, I shall not have written in vain.

AMERICAN CORRESPONDENCE.

ON TESTING SILVER SOLUTIONS.

On Testing Silver Solutions.—Notwithstanding the amount of instruction there is made accessible to the photographer of the present day in the way of books, periodicals, exhibitions, &c., there is a great deal of walking in the dark; and in no part of his manipulations is the photographer more puzzled and bewildered than in the management of that mysterious mixture, the nitrate of silver bath. The more of a mixture there is made of it the more mysterious it becomes too. I am constantly receiving complaints from parties like the following:—

“What is the matter with my nitrate solution, that I cannot get intensity? I have tested it with the hydrometer, and it indicates 40, 50, or 60 grains strong; and yet, to save my life, I cannot get a proper negative with it.” Another:—“Please examine the prints I send you. They

have every evidence of a weak silvering solution, and yet I habitually keep up the strength of my silver to 10 or 45 grains. Why the trouble? Is my hydrometer probably at fault?"

Now we all know, or we should if we do not, that a bath when new—40 grains strong—will work with perfect satisfaction; but after it has been used for a time it fails to give good results until the hydrometer indicates 45 to 50 grains strength. The reason of this is, that the hydrometer shows only density or specific gravity; and it is a common mistake to suppose that a hydrometer will tell the actual amount of silver in any given solution, no matter what the density of that solution is.

The silver test, or hydrometer, in common use in this country, consists of a sort of beaker glass, for holding a quantity of the solution to be tested, and a mercury bulb with a glass scale attached. We call it the argento-hydrometer. The scale of the argento-hydrometer is prepared in the following manner:—It is first floated in pure water at 60° Fahrenheit, and the point to which it sinks marked; this is the zero of the scale (see fig. 1). It is then placed successively in solutions of the same temperature, containing 10, 20, 30, &c., grains of nitrate of silver to the ounce, and the different points to which it sinks carefully marked. The points are, when the scale is to indicate 1 grain for each degree, the 10, 20, and 30 degrees, &c., of the scale. The intermediate single degrees are put in by simply dividing off into ten equal spaces.

This instrument, thus prepared, can be used to test any other pure solution of a soluble salt; but, as these solutions vary very much in density when containing the same number of grains of the different salts dissolved in them—for example, a solution containing 20 grains of chloride of ammonium does not test the same as one containing 20 grains of hypo soda—a table of corrections is required. Such a table accompanies the argento-hydrometer. The instrument has no discriminating or selecting power; hence, if the two solutions just named were mixed together, no table could be made which would give, from the indication on the stem, the number of grains of the one, and the number of grains of the other, contained in each ounce of it.

When a silver bath is new, the reading of the hydrometer can be relied upon; but in working, as every plate abstracts silver by the formation of iodide and bromide of silver in the collodion film, and adds nitrates of potassa, cadmium, &c., according as iodide and bromide of potassa cadmium, &c., have been used as excipients, we have an impure solution, in which the above salts, as they increase its density, test by the hydrometer as so much silver, and we cannot tell, from its indications, how much nitrate of silver alone it contains. The older the bath, the more impure the solution, and the more unreliable this manner of testing becomes. The reason of this I have given above.

It is well known that different bodies of the same weight are of different sizes; and, again, that bodies of the same size have different weights—as, for instance, a pound of lead is smaller than a pound of wax, and a piece of lead weighs more than a piece of wax of the same size. When the weights of different bodies are compared to the weight of equal volumes of water, we have what is called their specific gravity. The specific gravity of gold is 19.3—that is, 1 cubic inch or foot of gold weighs 19.3 times more than a like bulk of water; and when the specific gravity of an acid is given as 1.4, it means that a cubic inch, or a pint, or any other measure of it, weighs 1.4 times more than an equal measure of water. We have, in the hydrometer, a quick means of finding specific gravities of liquids. If we float it in liquids of different densities, it will sink to different depths in them, but always so far until the weight of the volume of displaced liquid equals the weight of the

Fig. 2. which the above salts, as they increase its density, test by the hydrometer as so much silver, and we cannot tell, from its indications, how much nitrate of silver alone it contains. The older the bath, the more impure the solution, and the more unreliable this manner of testing becomes. The reason of this I have given above.

whole instrument. As the same liquid varies in density, according to its temperature, it is necessary to have a standard, which is usually 60° Fahrenheit, and all solutions should be made of the proper temperature before testing.

There are methods, however, of ascertaining the quantity of silver in any solution, pure or impure; one of the most accurate of which is, the one introduced by Dr. Vogel, and which, I believe, you have described to your readers. If you have not, I hope you will bring it to their attention.

There is also another accurate instrument. Dr. W. H. Pile, of Philadelphia, manufactures a "volumetric silver test," which is much simpler than Dr. Vogel's, as it consists of but a single tube, and is almost as correct. In using it,

it is only necessary to fill the tube A to the point O with the silver solution to be tested; then add the test solution (made by dissolving 140 grains of well-dried rock salt in 1 pint of distilled water at 60° Fah., and adding to the clear solution 2 grains of bichromate of potassa), freely at first, afterwards gradually, closing the tube with the thumb, and shaking well after each addition, until, after allowing the precipitate to settle, no more cloudiness is produced by a drop of the test. The level at which the liquid in the tube stands gives the number of grains of nitrate of silver contained in each ounce of the solution (see fig. 2).

Fig. 1.

There is also an "easy method of testing, which is within the reach of every photographer," for which I am indebted to our eminent Philadelphia chemist, Mr. James F. Magel, as well as for some of the hints above. The only articles required are, an 8-oz. narrow-mouth bottle, a graduate glass, and some common table salt.

The test solution is made by dissolving 55 grains of well-dried salt in 1 pint of water. Measure into the 8-oz bottle $\frac{1}{2}$ oz. of the silver solution, and add to it carefully, from a clean graduate glass, shaking well after each addition, the test solution, until no cloudiness is produced. If it takes 1 oz. of this solution, it contains 10 grains of nitrate of silver to the ounce; if 2, it contains 20 grains; and so also of fractional parts: $3\frac{1}{2}$ oz. shows $31\frac{1}{2}$ grains; $3\frac{1}{2}$ oz. 35 grains, &c. As every 1 oz. of solution used shows 10 grains of nitrate of silver to the ounce, it is only necessary to multiply the number of ounces, and parts of an ounce, by 10, to give the required result. A 2-oz. graduate glass is the best size to use, as it is so graduated as to show $\frac{1}{2}$ oz. readily; and, as every $\frac{1}{2}$ oz. of test solution equals $1\frac{1}{2}$ grains of nitrate of silver, this test is sufficiently accurate for all practical purposes. If about the number of grains in the solution is known, add at once nearly the required quantity of the test, and afterwards small quantities at a time. Supposing it to contain about 40 grains, add $3\frac{1}{2}$ ounces of the salt solution, shake well—and, towards the latter part of the process, it requires hard shaking to get the chloride of silver to precipitate out and leave the liquid clear; then add, from an exact measured ounce, about $\frac{1}{2}$ at a time, until the precipitation is complete. Add the quantity used to the first $3\frac{1}{2}$ ounces, multiply by 10, and we have the number of grains of nitrate of silver.

It frequently happens that, before sufficient of the salt solution has been used, the precipitated chloride of silver is quite hunky; but, when shaken up, after the addition of the last required quantity, it becomes much denser, and settles rapidly to the bottom. This is a good indication of enough solution having been used. One or two trials of this process will give all the experience required to enable any one to do it easily and quickly.

If the silver solution contains ammonia—an ammonia-nitrate solution, as it is termed—after measuring off a $\frac{1}{2}$ oz. of it into the 8-oz. bottle, make acid with a little pure nitric

acid, and then proceed in precisely the same way as above explained.

Dr. Vogel's, Dr. Pile's, and the "easy" methods cannot be used if the solutions contain salts of lead or mercury; but as these salts are not used by photographers, it is not necessary to give processes by which such solutions can be tested, requiring, as they do, some knowledge of chemical manipulation.—Yours truly,
EDWARD L. WILSON.
Philadelphia.

PHOTOGRAPHIC TRANSPARENCIES FOR THE LANTERN.

Our excellent contemporary, the *English Mechanic*, contains a capital series of articles on colouring magic lantern slides. The right to reproduction is reserved, doubtless for separate republication. We venture to extract, however, some remarks on photographic slides, which, whilst we cannot altogether endorse in all respects, will be found suggestive to our readers. Having described his mode of treating outline drawings, he proceeds:—

"Now for the photographs; and here I fear I am intruding on 'Tom Tiddler's ground,' but not 'picking up gold and silver;' so I trust Tiddler and Co. will be merciful, when I affirm that for dissolving views I greatly prefer a highly-finished hand-painted slide; and I entreat my friends to believe, that after some little experience as an exhibitor, I am strengthened in my preference by the opinion of some very excellent connoisseurs. Notwithstanding, I feel strongly with all classes of photographers. Some years ago, when I could not handle my pencil so deftly, I myself was a photographer, and quite enthusiastic; so fascinated was I that I spared neither fingers, personal or house linen, but sacrificed all to the cause, to the intense disgust of the ladies who had the great misfortune to be interested in my belongings. For a long time I encountered a series of awful failures; but as I have a habit of sticking doggedly to anything that promises social enjoyment, if I once take it in hand, as a matter of course I was at length tolerably successful (as every one must be, it head, heart, and hand work well together). At first portraiture seemed to hold out no end of delight; but I soon lost patience with this; not that the bath, the developer, or the light were so often in fault as the sitter. It was *there* the chief bother lay. Often when I had obtained a really good picture, it did not please; something was wrong about the eyes, nose, or mouth; it was 'sour-looking,' and the expression was not good. In a word, it 'wasn't like'; so I determined to devote myself exclusively to landscapes. I began with the memorable folding camera of poor Archer, carrying my bath, solutions, glass, &c., within it; and manipulating inside the camera through sleeves at the sides. Every one now has his own pet method; but, with a few slight improvements, I would work the above against any I have ever seen since. (My pictures were 10in. by 8in.). As I recall the old absorbing amusement and the old companions in it, my heart warms towards the whole brood of photographic artists. But I was not satisfied; the cutting sharpness of the glass negative always impressed my eye unfavourably, so I abandoned glass for French negative paper, and it gave me what I sought. It was light, portable, not subject to breakage; creasing was easily prevented; it required a longer exposure, so that objects in motion were not so great a nuisance as before; and it yielded better *half shades*, greater harmony, and other effects which are so prized by the landscape painter, and which *make* a picture. I advance all this to prove that I do not write at random, and that I have some practical knowledge of the art. The accuracy of photography is beyond all praise; that is its strength; but it is certainly wanting in half lights, more especially when reflected from all shades of green, red, &c., in the shade; that is its weakness. In colouring photographs for the lantern the artist cannot leave the blank masses of foliage and other void tracts in shadow; he must do something

with them, and, for my part, I would rather paint ten pictures first hand than *do* that something. True, they *can* be exhibited uncoloured, but to judge of the effect, place in the slide-holder of the other instrument a first class hand-painted view, and dissolve the uncoloured photo. into it; do this before a good sprinkling of spectators, and take *their* verdict. This is the way in which I have arrived at my conclusions, remembering always that if I exhibited only to please my own eye, it was but a sorry pastime; but I myself like the paintings best. I have been told that some prefer cold marble to warm flesh and blood; if this should be read by any who do, I hope they will not be 'werry down' upon me for declaring that I do *not*.

"I have attempted to reproduce good engravings, mostly small ones, by the aid of photography, to avoid the labour of outlining, particularly that of reducing, but the 'hatching' had a fearful effect on the screen, the picture looking as though some gigantic spider had spun his web over it. However, some tolerable photos. are sold by the houses already mentioned, and I recommend them also to the friends I am now especially addressing. Use the same colours, &c., and lay your tints lightly yet decidedly; do not attempt deep shading, but imitate the colouring of the stereoscopic pictures, and *never* use the knife or etching point.

"To photographers I would say, with all due deference, print your positives on glass with albumen, *not* collodion; if you exhibit with oil, and not the oxyhydrogen light, you will soon discover the vast superiority of the former.

"Another objection to photos. is the protecting varnish; it greatly embarrasses the artist. I prefer the freedom which the pure surface of the glass affords.

"Still, for astronomical and microscopic objects, machinery, statuary, and architectural elevations, photography is, and must ever be, unapproachable by the hand of the draughtsman.

"Note.—Water-colours are said to be most available for tinting photos. I have given the system a fair and patient trial, and cannot recommend it for glass painting; but I have experimented on photos. with Judson's simple dyes, tinting them as the stereoscopic pictures. This is not difficult, and the result, if not acceptable to the painter's eye, is bright and pretty, albeit too closely resembling the colouring of toy books."

PRACTICAL HINTS ON THE PRESERVATION OF NEGATIVES.

BY WM. ENGLAND.*

UNDERSTANDING from Mr. Rejlander's remarks at the January meeting of the Society that he intends inviting discussion on a subject of great interest to photographers (*viz.*, the causes of an occasional form of injury becoming apparent in their negatives, and popularly known as the splitting of the film), I am induced to offer a few suggestions, hoping that other members may likewise be disposed to give us the benefit of their experience on this important question.

Although I have given considerable attention to this subject, I must confess my inability to discover the real cause of these disastrous appearances, and am undecided as to whether the fault lay in the varnish or the collodion. In the majority of cases, I believe it originates in the latter; but the fault may, in some measure, be due to the use of a varnish of non-elastic character. One important cause of injury to the negative I have, however, found to arise from the accumulation of nitrate of silver in the film, as the result of its contact with the sensitized paper during the printing process. When the negative, no longer required in the frame, is put aside, the deliquescent nature of the silver and other salts tends to induce conditions favouring the absorption of moisture, which, without doubt, is one of the immediate causes of splitting of the

* Read before the Photographic Society, March 14.

film. The amount of silver which will thus attach itself to the negative during its continued use may be inferred from the result of the following experiment:—Some time ago, when proceeding to re-varnish some negatives which had become much worn, I poured into a flat dish several ounces of alcohol, for the purpose of dissolving off the old varnish; after immersion of the plates, I dried and re-varnished them in the usual way; but the negatives, on being placed again in the light, in order to obtain further proofs, speedily darkened to such an extent as to become useless.

The cause of this alteration may be readily understood, when we take account of the circumstance that the alcohol had become impregnated with the silver existing in the old varnish; and I was strengthened in this belief by observing that some of the spirit, on being applied to paper, and exposed to sunlight, quickly became discoloured. Since these results were noticed, I have always taken the precaution, whenever negatives are removed from the printing frame, and about to be stored away, to thoroughly clean the face with a soft cloth dipped in water; and, after removing all injurious matters, rub dry again with a clean cloth; and, as a further precaution, apply, with a tuft of cotton-wool, a little encaustic paste, made by dissolving white wax in turpentine to about the consistence of cream. The negative thus treated will be found to withstand the action of moisture from the atmosphere; and another advantage which follows the application of the wax is, that the film does not seem to lose its nature or become rotten. It is, of course, unnecessary to say that negatives should at all times be kept in the *driest* apartment in the house.

Since taking the before-mentioned precautions, I have rarely met with a damaged negative; and the only possible drawback to this method is that, in the event of there being any retouching on the film, this work will have been effaced. The practice of revarnishing an old negative when it has become worn is thus a great protection against the film splitting; and I would recommend that, as often as this is adopted, care be taken to wash the film with *several* applications of alcohol after removing the old varnish, or the darkening already mentioned, on the exposure of the negative to light, will certainly cause its destruction after a few proofs have been obtained.

It may now be asked, What is the best to be done with the negative which has met with the injury under discussion? It is very annoying on taking up a valuable negative which has been carefully stowed away to find that it now presents, on holding it up to the light, a series of reticulated lines of every possible form. Various substances have been proposed with which to fill up the cracks in these broken films—such, for instance, as lampblack, plumbago, &c.; but by far the best substance for this purpose is, in my opinion, Indian ink. This pigment is rubbed up with a little water, and applied with a soft piece of silk, working it well into the fine lines, and, whilst still moist, wiping off the superfluous ink, so that, if properly done, no mark will now be visible to the eye. This method is preferable to the use of lampblack, for the latter, being in the state of fine powder, soon works out of the cracks; but I have seen negatives “doctored” in my way from which upwards of a hundred proofs have been obtained, and which promise to yield hundreds more, without showing any signs of deterioration. This scheme, which is only so far satisfactory as relating to mischief already done, I cannot, however, rest satisfied with; for whilst the original cause remains undiscovered, it is lamentable to think that negatives which may at some future period possess great historical value should be thus perishable. I am inclined to think the fault cannot be altogether in the collodion,—witness the transparencies, which have been in existence for many years; also negatives not varnished seem very durable. I have even now some duplicates taken fourteen years ago,

which are as perfect as on the day they were first taken. An example of the successful application of Indian ink to a cracked negative film is submitted for the inspection of the meeting.

[The illustration consisted of a pair of prints; one with fine black lines apparent, showing the result of printing from the cracked film; and the other, in the restored condition of the negative, after the cracks had been filled up with Indian ink.]

THE FOTHERGILL PROCESS WITH GALLIC ACID.

MR. BEASLEY gives in the Society's Journal the following details of his mode of working the Fothergill process:—

The Collodion and Sensitizing Bath.—I always use patent plate glass cleaned with tripoli and spirits of wine. The collodion should be old (about three months) and porous, giving a creamy film; a new horny collodion is quite unsuited for this process, and fails especially when the acid-pyro development is resorted to. After coating the plate with collodion, the film should be allowed to *set well* before immersion in the silver bath, which may be a 35-grain solution made slightly acid. The sensitized plate is then put into a dish of water (one pint of distilled water being made to serve for two 10 by 8 plates), and gently rocked for a minute or so, and taken out and drained.

The Preservative.—Albumen solution composed of the white of one egg beaten up with one drachm of distilled water and eight minims of ammonia, using a silver fork. I prefer keeping it of this strength, and dilute it for use by adding two ounces of distilled water to one ounce of the stock albumen. Or I proceed as follows:—Add a few drops of glacial acetic acid to the drachm of water and the white of one egg, stir well together for a few minutes, filter through muslin, and render alkaline with twelve minims of ammonia. This plan gives a solution which is at once clear and brilliant.

One or other of these solutions is then applied to the plate, and made to flow evenly over the surface with a gentle motion. After allowing the albumen to remain on for about two minutes, it is washed off under a tap or india-rubber pipe. Three minutes may be sufficient; but the plates cannot be washed too much at this stage of the process. They are then allowed to dry spontaneously in a dark box or cupboard, using a little chloride of calcium to absorb the moisture.

Exposure and Development.—For a well-lighted view I should give about eight minutes, with a single view lens, $\frac{1}{2}$ in. stop, and when away on a three weeks' tour never less than ten minutes. Before proceeding to develop the plates it is advisable to pour on a mixture of alcohol and water, to soften the film, and afterwards to wash this off with water. The developer is composed of—

Pyrogallic acid	2 grains
Citric acid	$\frac{1}{2}$ grain
Water	1 ounce

to each drachm of which is added at the moment of use one drop of acid silver solution, consisting of ten grains of nitrate of silver and twenty grains of citric acid to the ounce of water. The image appears very slowly, being retarded both by the albumen and by the acid in the pyro; but I prefer a gradual development, and to make a separate process of the intensification, which is conducted by gradually increasing the amount of silver present in the developer. If the acid in the pyro be omitted, the image appears more rapidly; but in the event of the full exposure having been given, the picture is liable to be flat, especially when a long-focus lens has been used. The time ordinarily occupied in the process of development is half an hour, and the plate should be kept in motion, for which purpose I am in the habit of using one of Mr. Keene's swinging shelves. Fix with hyposulphite of soda.

Alkaline development may be resorted to when the plates are not more than a fortnight old; and the longest period during which I have succeeded in preserving them by the Fothergill process is six weeks. When I wish to prepare plates for long keeping, I adopt the following slight modification:—Instead of *partially* washing the sensitized plates in distilled water, I wash them thoroughly under a tap (two minutes or longer), and after applying the albumen, wash them again in the same manner. I then pour over the plates a 3-grain solution of gallic acid, which is allowed to soak well in, and after draining off the excess, dried as before. Every dry-plate worker knows the extraordinary degree of permanence which is gained by the use of gallic acid; and the plates taken out by me to Gibraltar were prepared in this manner. They are rather slow; but the exposure may, if desired, be considerably reduced by alkaline development. The longest time that I have ever kept one of these plates was three and a-quarter years between preparation and exposure. When I want a quicker process I adopt another slight modification, viz., that of adding two grains of bromide of cadmium to the ounce of collodion, and leaving the plates for ten minutes immersed in the silver bath. Thoroughly wash, and apply albumen as before; well wash again, and develop with *alkaline* pyro. I have not yet tried the gallic acid on these plates, but fear the sensitiveness would be greatly diminished; they will not keep more than a few weeks without it; but a newer collodion may be used, and they are very rapid. The good effect of the application of albumen can be seen by coating half a sensitized plate, washing off again, exposing, and developing. Albumen may likewise be used advantageously in other dry-plate processes before applying the preservative.

COFFEE AND OTHER DRY-PLATE PROCESSES,

WITH PRACTICAL DETAILS

OF A NEW DEVELOPER GIVING EASE AND CERTAINTY.

BY A. DE CONSTANT.

PRELIMINARY REMARKS.

It is said that a gentleman very distinguished in practical photography—to wit, M. Braun, of Dornach—declared once upon a time that, having expended to no purpose considerable sums of money in the endeavour to find a good dry collodion method, he should henceforth confine himself exclusively to the employment of a wet process.

This statement, made by the head of, perhaps, the largest industrial photographic establishment in the world, is calculated to intimidate seriously the timid disciples of dry processes, and those disposed to join that band; and it really becomes a matter of necessity to decide whether a means so convenient and useful shall be altogether abandoned. In the first place, however, I would express a very grave doubt as to whether M. Braun ever did pronounce so severe a sentence against the use of dry collodion; for, if I am not mistaken, his operators have always worked with wet plates, the choice of this method of operating being imposed upon him rather by the exigencies of his enterprise than from any dislike on his part to a dry process. And, indeed, is not the reason for the practice of wet photography at once accounted for in the Braun establishment by the fact that the numerous employes, who travel to the most distant countries at an enormous outlay, must know immediately the true result of their labours in order that they may repeat, if necessary, their exposures before quitting the spot? for when it is a question of an interesting view, several clichés of different dimensions have frequently to be obtained.

But besides this, the brother of M. Braun—whom I have met on his rounds fortified with rare courage and skill to withstand the disagreeables and inconveniences occasioned by his improvised tent and laboratory—has himself assured me that were he cognizant of a dry process so certain and efficient as the one by means of which my negatives were obtained, he should be happy to avail himself of it very

often. Thus there is yet hope for believing that the dry process is not irrevocably condemned at Dornach.

But another reproach against dry plates has been made by M. Moll, who advocates their banishment by photographers. Without disputing the fact that he has obtained by their aid some very excellent results, this photographer enters into a statement of the tedious and lengthy nature of the preparation of the plates, enumerating, one after the other, the many manipulations which are necessary. M. Moll easily arrives in this manner at a total of time and trouble which he represents to be much greater than that involved in the manipulation of wet plates out of doors. Now we know very well that he who says too much says, indeed, nothing at all; for if one occupies, as in my own case, a couple of hours for the preparation of a dozen dry plates, then their subsequent exposure (even in localities of a most inaccessible character) may be regarded as but a promenade, and a dozen or fifteen views are obtained at the cost of no trouble whatever, the plates, moreover, being capable of development as easily as wet collodion negatives. I should be very sorry, for my own part, if, to do the same amount of work, I were compelled to go forth with an assistant, encumbered by an enormous quantity of baggage requiring to be set up and taken down for each view, and to be inconvenienced, furthermore, by the heat, and other well-known difficulties. And I fully believe that if, in the two cases, I carefully compared the time, labour, and cost expended, the wet process would certainly come off second best.

There is, indeed, only one serious argument that can be maintained against the dry mode of working; viz., the uncertainty of the result. Now, as regards this point, I do not hesitate to affirm that the mode of operating I now employ is so sure and simple as to rival, in these respects, the wet-plate process, and to yield prints of even superior quality to negatives taken in the ordinary manner.

Then, touching the preservation of the dry plates for a long period in good condition. This has already been guaranteed by *bona fide* traders, and affirmed by operators in whom unbounded confidence may be placed; and if to these I may be permitted to add my own experience, I would say that plates produced by the method I advocate may be kept without diminution of sensitiveness, or other alteration, for a period of two months or more. And if I can sufficiently rely upon the experiments which I have made upon the subject, it is upon the nature of the collodion alone that this question depends.

If I were asked to point out from among the many dry processes that which I considered the most efficient, my reply would be to the effect that for some time past photographers have given too much consideration to the question of rapidity, for a long experience of the matter has proved to me that very rapid processes are, as a rule, uncertain, and beset with practical difficulties. If one wants a simple and certain process, it is inadvisable to bargain for a very short exposure, for the artistic effect will certainly not lose by a few seconds more of pose. In general, it is the custom with the greater number of dry processes to calculate the exposure at four or five times that of a wet plate, conditions and circumstances being the same. But, by employing certain preparations, and especially those in which gum plays a part, the period may be reduced by one-third, or even one-half, without jeopardizing the certainty of the result. This reduction appears to me sufficient, and it would be wrong, to my thinking, to press the point of rapidity any further. The great utility of dry collodion for copying pictures and other works of art necessitating long exposures, its superiority over wet plates in the rendering of distance, and certain fineness of detail, ought to compensate for any lack of rapidity, and render it indispensable to every operator if, by simplifying and improving the method, we are enabled to place it within the reach of all. This, indeed, is the task to which I am about to address myself in publishing, in all its details, a process which will, I believe, fulfil to the utmost the conditions I have just pointed out.

In speaking thus, I do not wish in any way to condemn the works of others, but, on the contrary, hold that everybody should practise that which he finds the most successful in his own hands. Since the time—now upwards of a year—that I have exclusively worked with the process to which I have given the name of Coffee-Gum Method, and which I have experimented with in almost every phase, my results have been so exceedingly satisfactory that it is a pleasure to me to place my experience at the disposal of those of my brethren who may feel disposed to give the method a trial. And by way of encouraging such as may desire to follow my practical instructions, I would mention the circumstance that, during the past month, I have used more than a hundred coffee-gum plates in the reproduction of difficult pictures and landscapes of every kind without experiencing a single failure that could be ascribed to the process itself; while, from the whole number, but three or four negatives, at most, had to be put on one side. I doubt very much whether I should have obtained a similar result had I been working with the wet process.

But I will now proceed to the details of my method.

§ I.—THE CLEANING OF THE PLATES.

I have tried many ways of cleaning glass, but none has appeared to me so simple and efficacious as that described by a correspondent in the *PHOTOGRAPHIC NEWS*, which consists in boiling for a certain time both old and new plates, whether varnished or not, in an aqueous solution of soda, made by dissolving half a pound of soda in fifteen litres of water. The plates are easily cleansed; and, as soon as the solution has been allowed to cool, they are taken out one after another, and carefully rinsed under a jet of water; when drained, and the last drops of moisture have been removed by means of blotting-paper, they are packed up, and a simple polishing with alcohol at the moment of employment then suffices to render them ready for use. If one has plates which are somewhat more difficult to clean, I would recommend a mixture of fine Tripoli powder with three parts of water and one of nitric acid. The glass is rubbed on both sides with a pad, and the mixture allowed to dry, and remain upon the plate until the latter is required for use. This preparation, when dry, may be removed very rapidly, the plates being first freed entirely from the dust, and then finally polished with alcohol.

§ II.—THE PRELIMINARY COATING.

It is generally accepted that the application of a preliminary coating renders unnecessary any severe polishing of the plate, and prevents also the rising or detachment of the collodion film, an accident to which dry plates are sometimes prone when again moistened previously to development. In many studios, indeed, the precaution is used even for wet plate manipulations, as an assurance against imperfectly cleaned plates. As I believe it preferable in all instances to work with none but clean plates, the saving of time did not influence my action; but I have found by experience that in any process where gum is used, the application of a preliminary film is indispensable. For this reason I invariably apply a coating of this kind to my plate, selecting for the purpose albumen. I am glad to see that a dilute solution of this substance, which I proposed some time since, has been generally adopted; one part of albumen well beaten, and then allowed to stand, is, after decanting, mixed with twenty-five or thirty parts of water, a few drops of ammonia being subsequently added thereto. Although a solution of this kind may be preserved for some time, still it is better always to employ the mixture freshly prepared. It is best to give the last polish to the glass plate immediately before applying the albumen, as the latter is found to spread more uniformly upon a dry and well-polished surface.

The plate is rested upon a horizontal support, and the well-filtered albumen poured freely thereon across the whole breadth of the glass in sufficient quantity to cover the entire surface, care being taken to pour gently, and not from

too high a point, so that the formation of air-bubbles is avoided. Then, with one sweep of a glass rod held horizontally, the liquid is spread over the plate, the superfluous liquid being removed and allowed to run to waste; if there are any spots near the margin of the plate where the albumen is repelled, the defect is remedied by means of the rod, which must always be kept perfectly clean and free from any previous trace of albumen. To ensure this, it is well to wipe the rod with blotting-paper after every manipulation therewith, and to keep it immersed in a vessel of clean water, which prevents the albumen from coagulating and falling in the form of dust upon a subsequent plate. When coated, the plates are arranged on end upon a sheet of clean filter paper in a locality sheltered from the dust, their position being changed after the first draining has taken place. Prepared in this way, after the expiration of two hours the dried plates are so clear and transparent that it is impossible to distinguish the coating of albumen at all.

The backs and sides of the plates are kept altogether free from any trace of albumen, and no fear need, therefore, be entertained for the welfare of the sensitizing bath. At the same time, the albumen film, notwithstanding its delicate nature, has always, I have found, imparted sufficient solidity to the collodion, while none of those spots and stains with which I was previously familiar when employing gelatine, caoutchouc, or concentrated albumen, have ever of late plagued me.

(To be continued.)

GUM-WATER ON NEGATIVES.

BY M. CAREY LEA.*

A NEGATIVE which, after it has been left to dry, is found to need a redevelopment with pyrogallie acid and silver, is exposed to a certain amount of danger of splitting in drying. Some collodions show this tendency to a much greater extent than others.

To meet this risk, it is commonly advised to flow the plate over with gum-water or with a solution of gelatine. As the solution of gelatine needs to be warmed, the gum-water is the most convenient, and is, I suppose, the most generally used, and it certainly does prevent the splitting.

But it is liable to a very grave objection. The plate must be varnished after gumming, because with the faintest trace of moisture the gum surface would stick to the silvered paper and ruin the negative. It therefore needs varnishing, and there is no difficulty in varnishing it apparently very well. Unfortunately, the varnish does not penetrate the film; the gum renders such penetration impossible, and, consequently, the negative has no sufficient protection. The protection afforded by the gum is very insufficient. Gum holds badly on glass, and is liable to scale off. So that a negative that has been gummed and varnished is in a peculiarly insecure state, and will not bear the least careless handling.

It is difficult to know what to do with negatives that are in danger of splitting. The gum is very objectionable for the reasons just given. It might perhaps answer, as soon as the negative is finished and washed, to flow it with alcohol until the water is well out, then varnish cold, and dry well by heat. This would seem likely to give a good result, and obviate all difficulties.

Recent Patents.

PHOTO-MECHANICAL PRINTING PROCESSES.

BY F. W. WINDOW.

In the following specification Mr. Window describes certain improvements he has devised in photo-mechanical printing processes, an important element in his improvements consisting in a plan of securing several printing plates from

* Philadelphia Photographer.

one negative, each intended to print a certain tint of the picture, a perfect result being obtained by several printings with perfect register. A second improvement consists in producing a photographic image by the action of light through a negative upon a hygrometric substance, as in Joubert's enamel process, and then transferring this image to a lithographic stone to act as a resist. A further improvement consists in a modified photo-collographic process. The specification is as follows:—

It is well known that various processes have been devised for obtaining metallic printing plates or surfaces in intaglio and in relief, and also for obtaining such surfaces upon stone and upon gelatine or other colloids by photography. Many of the printing plates or surfaces so produced yield satisfactory results when the design or subject is in line, or in coarse grain or stipple; but they fail to give satisfactory results when the design or subject is in graduated tints like an ordinary photograph, such proofs being usually deficient in delicacy or perfect gradation in the half-tones, or deficient in strength and vigour in the shadows.

Now, the first part of my invention consists in an improved mode of obtaining proofs or impressions on the plates or surfaces obtained by photographic agency, of whatever kind or nature such plates may be, and by which mode I am enabled to produce a considerable degree of half-tone, combined with great vigour, in the subject to be reproduced.

I carry out the first part of my invention by producing two or more plates instead of one from the same negative, each of which plates has received a sufficient degree of exposure. By this means I divide the subject in graduated tones into an imaginary series of "flat tints"; and if the process be one which merely yields a surface giving a flat tint or impression, I form as many plates as I have assumed the subject to have tints, each of such plates having register marks obtained directly from the negative. These plates are printed in succession in a mere or less transparent ink of a depth calculated to give the requisite tint; and, as each plate contains different portions of the subject—the first containing the whole of the subject, and the last only the dark touches to form only the deepest shadows—the whole subject is ultimately produced with a degree of delicacy proportionate to the number of surfaces employed.

When the process employed is susceptible of yielding surfaces which give a certain degree of half-tone or impression, a smaller number of surfaces is necessary, as each surface furnishes several of the imaginary tints into which the subject is assumed to be divided.

An analogous process is also applicable to the production of proofs in colour by using more surfaces, and stopping out from each, or from the negative which produces them, the colours complementary to the colour that is wished to be produced. Thus, if it be desired to print blue, or colours which contain blue, all the parts of the picture which do not contain this colour must be stopped out, and so on for each elementary colour and its composites.

The second part of my invention consists in an improved mode of obtaining printing surfaces on stone or zinc. I effect this by printing, by means of a negative, a positive image of the subject to be reproduced in a compound which will form a resist upon the stone, and which will absorb moisture from the atmosphere—such, for instance, as a mixture of albumen and honey, or gum and honey, rendered sensitive by a chromate, and spread upon paper. After exposure, I allow this mixture to absorb moisture in the parts not exposed to light, which then become sticky, and adhere to the stone when the exposed proof is laid down upon it and submitted to pressure; or I print a negative image on gelatine, or other analogous colloid, from the subject itself or from a positive obtained from the negative of the subject, and after printing I lay down the insulated proof upon a stone or zinc plate, after wetting it and scraping out the air and superfluous moisture; I then wash away the parts not acted on by light. The stone supporting the image so obtained is washed in a solution of alum and allowed to dry. When dried, it is inked up in the usual way; the gelatine image is removed by water and a sponge, and the fatty image remaining is treated in the usual way for lithographic printing.

I also form a printing surface upon stone or other surface in the following manner, but I lay no claim thereto:—I spread a layer of gelatine, alone or mixed with sugar or some other colloid, upon smooth paper which has previously received a thin,

smooth coating of gum arabic and sugar, or gum arabic and glycerine. The gelatine coating may be composed of—

Gelatine	3 parts
Sugar	1 part
Water	9 parts.

If the paper or other surface so treated have to be used at once, one-half part of bichromate of potash in fine powder may be added, together with twenty drops of glacial acetic acid to each imperial pint of the solution—the object of such addition being to cause the gelatine to assume the insoluble condition without destroying its sensibility and other properties, as is well understood; or the paper may be prepared without the addition of the bichromate and acid, and may be made sensitive when required for use by immersing the paper in a solution of the bichromate and acid, such solution being of the strength of about five per cent. of the solid salts. When dry, the sensitive paper, prepared in either way, may be printed until the subject be seen fully up, and must then be washed in very cold water until all the chrome salts are removed.

At this stage the gelatinous film will have left the paper if prepared, as directed, with a preliminary coating of gum, and will have floated off. It may be re-attached, the printed face being upwards, as directed, for the application of the printed paper in known methods—that is to say, by laying it out upon a porous lithographic stone, and scraping out the water and air from between its surfaces. I prefer, however, to mount it by the same means upon a flat plate of zinc or copper which has been well ground, or upon a finely-grained or pumiced plate which has received a fine coating of India-rubber and gum dammar, or other resinous bodies of the like nature, dissolved in benzole, so as to retain the gelatine film upon the plate during the operation of printing, as is well understood. The surface, when so applied, is ready to receive the ink after being dried by means of blotting-boards.

When in the state containing the proper amount of moisture it will ink up, as in Tessie du Motay's and other analogous processes. By the use of prepared paper I can prepare this surface readily, and without any trouble in drying, and the surface so formed is printed under the negative with greater ease than one upon a rigid support.

IMPROVEMENTS IN PHOTO-ENGRAVING.

BY WALTER B. WOODBURY.

In the following specification Mr. Woodbury describes a method of making photo-relief plates available for ordinary copper-plate printing, by giving them an ink-holding grain; and also a method of producing designs like water-marking in paper.

These improvements consist, firstly, in the preparation of a gelatine relief produced photographically by well-known means from a negative of a sketch, design, or drawing in black and white, the outlines and shading being produced in lines or dots (or both), without washes or half-tints, and the obtaining from such gelatine relief, when dried, a reverse in any soft metal by hydraulic, screw, or other pressure; such plate to be afterwards used as an engraved plate for printing from in fatty opaque inks, as in the present method of printing from ordinary engraved plates. If necessary, an electrotype may afterwards (where large numbers of prints are required) be made from the soft metal plate.

Secondly, in an improved method of obtaining a granular surface, such as would give an ink-holding ground where the photographic negative possesses merely gradations of light and shade, in contradistinction to the mere black and white lines and dots before mentioned. This I accomplish by mixing with the gelatine and bichromate (instead of colour in a fine state of subdivision, as used in the carbon process) a coarse granular substance or powder of the same description—that is to say, a granular substance or powder that will take the place of the colour as now used to prevent too deep an action of light into the bichromatized gelatine. This, when acted upon by light transmitted through the negative, will produce a relief having a granular surface, and possessing the necessary qualities for producing an ink-holding ground. In some cases I partially dry the gelatine relief, and dust over it a coarse powder, such as emery, which, while the relief is in a semi-dried state, will adhere only to the parts representing the dark portions of the design, and will, consequently, give to the soft metal plate produced by pressure therefrom a corresponding granular effects

which is usually wanting in such plates as are now prepared, but which is necessary to a successful result when printing with the fatty opaque ink; or I give the plate two coatings of the granular gelatine mixture—the first holding a fine and the second a finer powder, the latter, after washing, holding only the coarser grains which represent the deeper blacks of the picture.

The third part of my invention consists in an improved method of producing direct from the gelatine relief itself, by pressure in contact with other substances or materials (such as cardboard, leather, papier-mache, paper, &c.), designs on these materials, and in the particular method of preparing such gelatine reliefs, which I effect as follows:—A film of gelatine colour and bichromate is exposed to the action of light under a photographic negative or positive, and the exposed side of the said gelatine film is brought into contact with a sheet of copper, steel, or zinc under water, and the two surfaces are pressed in close contact to exclude the water; the plate, with the gelatine surface adhering to it, is then placed in hot water, which will remove the greater portion of the gelatine, leaving the design in relief on the surface of the plate. It is then dried, and this plate, when passed through a press in contact with the cardboard, leather, or other substance or material, will reproduce the design thereon, and when paper is pressed in contact therewith it will produce, by compressing the fibres, a design similar to that known as a water-mark.

Having now described the nature and object of my said invention, together with the manner in which the said is to be or may be performed or carried into practical effect, I wish it to be distinctly understood that I claim as my invention—

Firstly, the use of metal blocks obtained from gelatine reliefs of subjects in black-and-white, or, where no half-tones exist for the purpose of printing from, in fatty opaque inks, as in the ordinary process of engraving; also in the use of electrotypes from the said blocks, where large numbers are required.

Secondly, the same method of producing a plate for engraving from, but substituting the granular relief, as stated, to produce the half-tone necessary in subjects which are not composed of mere black-and-white lines or dots, but contain what are known as half-tones.

Thirdly, the method hereinbefore described of obtaining such dry granular gelatine reliefs from a subject in half-tone, the effect of the lighter or darker tones being represented by the greater or less quantity of granular material left in the relief after washing.

Fourthly, the use of the gelatine relief itself for the production, by pressure into other materials, of ornamental designs thereon.

And, lastly, the use of the metal plates bearing the gelatine relief attached, as above described, to roll or press in contact with paper to produce a design similar to that known as a water-mark.

Correspondence.

CARBONATE OF SILVER IN THE BATH.

DEAR SIR,—At the foot of the letter of "A. W. H.," in your number for the 10th inst., you invite contributions of experiences. I have just had an experience which seems somewhat analogous.

Three weeks ago I had occasion to go through the usual process of diluting, alkalizing with carbonate of soda, and sunning my silver bath; and, having filtered it, and strengthened, and rectified in the usual way, I filled the bath up for use (a whole-plate glass one). I sensitized some half-dozen quarter-plates, all which worked well; but having, in the course of the work, detached the heel of my dipper, I took out the silver solution to get out the piece, when I found that it had acquired a slight purple tint similar to that from permanganate of potash—or, perhaps, more like the tint an old gold bath sometimes acquires. A filtration removed the colour; and the excess of the first operation, which was bottled, shows no such colour.

Mr. Gill, on the same page, appears not to have seen the late make of cometless collodion bottles, in which the carrying down of the pouring stopper appears to me to produce the end he aims at, more neatly and effectually than his two half bottles do.—I am, dear sir, yours obediently,
J. L.

Rotherham, March 16th, 1871.

[When silver is reduced by the action of light, the solution

generally acquires a purple tint from fine particles of reduced silver, the colour disappearing on perfect subsidence. The peculiarity in the case of "A. W. H." was, that he obtained not simply the purple tint of reduced silver in subdivision, but a crop of purple crystals.—ED.]

DEAR SIR,—I beg to say that the old bath solution I operated on (in the attempt to revive by the carbonate of soda plan) had never been doctored in any way. The bath was originally composed of 35 grains of nitrate of silver to the ounce of water, slightly iodized, and acidified with nitric acid, and had done, in its time, good work.

I followed the instruction given by Mr. Brooks with the greatest care. The carbonate of silver dissolved entirely, and the solution was colourless, but was rather too acid, and was neutralized, sunned, and then faintly acidified with nitric acid. The result was, on trying a plate, as I described in my former letter.

The baths reduced to carbonate of silver had never been treated with permanganate of potash, so that the crystals can hardly consist of that substance. Moreover, these crystals formed in the bath appear to be quite insoluble in water, and we know that permanganate is readily soluble.

In my first letter it should have been "80 ounces of bath," not "80 grains of bath."

I enclose a rough print to show how the plate is covered with pinholes.—I remain, dear sir, yours truly,
A. W. H.

Dublin, March 20th, 1871.

[The supposition in connection with permanganate in the bath was not that it contained permanganate of soda, but that the addition of that substance had produced permanganate of silver, which is very slightly soluble, and crystallizes out in fine purple crystals.—ED.]

PAPER IMPERVIOUS TO MOISTURE.

DEAR SIR,—If Mr. Herve had read my letter with a little more care, I think he would not have made the mistake of stating that I had given a recipe for "sizing the backs of photographs," but for a "size to be applied to prints on plate-paper, so that they may be coloured."

In a previous letter I had given an opinion that, from my experience of its use, possibly by some similar application paper might be made impervious to water. Of course, it would have to be done either by the paper manufacturer, or by the albuminizer passing the paper through the solution so as to size both sides previously to its being albuminized; and, consequently, the photographer would have no more to do than at present.—Yours truly,
WM. MONKHOUSE.

York, March 20th, 1871.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

DEAR SIR,—The method that the Committee of Selection for photographs at Albert Hall intend to adopt appears, at first sight, to be most equitable and just towards all candidates for exhibition; but if we look beyond the surface I think you will admit that it is most unfair.

To illustrate what I mean, we will suppose the three usual classes of exhibitors A, B, C. A, who usually sends a large quantity of rubbish—say fifty frames; B, who sends a moderate number of fair, average good work—say twenty frames; and C, the cleverest and, as a rule, the most modest, sends a few gems—say four frames. The Committee intend to select half of each candidate's works. What follows? A, the greatest muff, gets twenty-five frames hung; and C (who, if merit received its reward—which, at exhibitions, unless it has a friend at court, seldom does—should have had all his pictures well placed) has two returned. Comment is unnecessary.—I remain, dear sir, in great haste, yours faithfully,
A CONSTANT SUBSCRIBER.

[Does not our correspondent base his case for comment solely on assumption? We have no reason to believe that any one sent in a large quantity of rubbish in the hope that some would be retained; nor have we reason to believe where the contributions were bad that any were retained. As we are informed, where other things were equal, about half the examples of each contributor were selected, excellence obtaining the preference; and, where this was adjudged to be quite wanting, contributions were rejected altogether.—ED.]

MOONSHINE PICTURES, ETC.

SIR,—If M. Ogier, Mr. Turnbull, and others would give us a little of their *practical* experience in getting effects by moonlight, instead of theory, we might all become rivals to Mr. Robinson. I cannot, however, agree with Mr. Turnbull in the opinion that Mr. Robinson's seascapes are compositions. There are difficulties to be overcome in composition photographs that are not, I think, appreciated by those who have not attempted them. For my own part, I confess to dislike to such things. The art is always too visible. From this opinion I would, in justice, exclude the works of Mr. Rejlander. That gentleman's efforts are to me the most delightful photographs I meet with, which I attribute partly to the fact that he never attempts *too much*. His efforts never exceed his means. Hence his art is less visible than in most works of the kind. The only thing that *looked* artificial in Mr. Robinson's seascapes was the moon. I do not appreciate the doubt and difficulties suggested by this gentleman's works. His titles do not affirm that his pictures are taken at or near midnight. I have myself, many years back, with simply iodized collodion and pyro, and such other appliances as were then in use, taken landscapes in the vicinity of the sea, at late hours on summer evenings, with cloud effects included. I was not then trying to obtain rapid exposures, and rather avoided those views in which much water was visible. But if, with the imperfect means then at my disposal, this could be done, I do not see why, with the more perfect chemical and optical means now to be obtained, there should be so many suggestions of "dodging." Many, who have never worked near the southern sea coast, are not aware of the superior quality of the light, and some, as in the "Gull" controversy, argue without having seen the works in question, which is more amusing than instructive. We must remember that most seascapes that have come before the public have been taken when the sun was high; but in Mr. Robinson's case his titles affirm that they are taken much later in the day, and in this lies much of the difference in effects.—Yours respectfully,

AN ARTIST AND OLD PHOTOGRAPHER.

CRACKING OF NEGATIVES.

MY DEAR SIR,—I shall feel obliged by your contradicting an assertion imputed to me in the journal of the 17th inst., on the subject of crackings in negatives, in which appears this remark, that "negatives on green glass escaped, whilst those on white suffered."

You must, therefore, have misunderstood me, or else it was a slip of my tongue, as I intended to have said, in answer to a question of Mr. Gordon's, who asked if the glass might not be the cause, that happily this was not, in my case, a point of difficulty.

In a small collection of negatives taken whilst at Constantinople, I first discovered these crackings, and these, singularly, are upon two sorts of glass, one bought at Constantinople, which is Vienna glass of a dark green tint, and the other taken out with me from a firm in Soho Square, both alike being subject to these crackings or splittings. I have only met with these markings in the Constantinople negatives, which were taken with a particularly sensitive collodion, bought there.

I should not trouble you at such length, only it is a curious fact that in a period of ten or twelve years I have never met with it before, and I have taken some thousands of negatives in Europe, Asia, Africa, and America, under all the trying and varying circumstances to which out-door photographers are subject.—I am, dear sir, yours truly,

FRANK MASON GOOD.

Hartley Wintney, Hants, March 21st, 1871.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.

We append the following additional details of proceedings at the meeting of this Society held March 14th, containing details of interest connected with the cracking of negatives. In the course of the discussion,

The SECRETARY read a letter from Mr. Grant as follows:—

"Abergavenny, Feb. 22, 1871.

"DEAR SIR,—Seeing in the last *Photographic Journal* that you invite absent members to say what they know about the

splitting of films, I beg leave to give my experience (though I am glad to say it has not been much) as to the cause.

"Of course, there may be, and *are*, other causes, but no doubt the commonest fault is not washing the film enough after fixing.

"The facts are these:—Three years ago, I went on a wet-plate trip up the river Dart, in Devonshire, and took about thirty negatives on small-sized plates. Owing to a scarcity of water at the time, I used to wash my plates when I came back (at the end of each day) with comparatively very little water; the result of which was that, at the end of about a fortnight after they had been varnished, they began one by one to be covered with vermicular cracks, chiefly *in the sky*; in fact, all began to crack in the sky, and I then spread more or less over the entire surface of the plate. When I found some of them beginning to crack, I did all in my power to stop the rest, by keeping them in a dry cupboard, &c.: but to no purpose, for at the end of six weeks there was not a single plate that was not destroyed. The cracks were very fine, mostly resembling fine hairs, and some of them could be filled up by rubbing in lampblack or soot.

"After this I took a few negatives, and washed them slightly, and the same thing happened. I used the same varnish throughout. Since then I have had but two plates cracked in this way, and these also had been but very slightly washed. I used the same varnish as on the thirty plates that cracked. I have never seen a dry plate crack in this way, though, from other causes, have frequently had the film fly to pieces on drying.—I am, dear sir, yours truly,

W. J. A. GRANT."

The SECRETARY also read a letter from Mr. Blair as follows:—

"I have never had any experience of the splitting of negative films taken on *glass*, although I have used a considerable variety of collodions; but the varnish I have chiefly adhered to is common shellac dissolved in methylated alcohol, and applied under moderate heat. I have had some collodions, however, that blistered and cracked on the application of heat in the process of varnishing. This evidently arose from the sudden contraction of the collodion in those parts where there was a very slight deposit of silver, and the collodion had no firm hold of the glass. I have seen collodion negatives on paper crack whilst drying them too hastily at the fire, particularly when mounted on a surface of rubber varnish, which softened under the heat."

Towards the close of the discussion,

The SECRETARY referred to two previous occasions when the subject of the cracking of negative films had come under the notice of the Society. At the meeting held in December, 1863, he had himself brought forward the subject by showing some negatives which had become covered with honeycombed markings whilst in his possession at the Royal Military Repository; and later (in August, 1864) he had pointed out a mode of restoring these plates by exposure to the vapour of alcohol, which will be found described in the *Journal**. At the May meeting, 1869, Mrs. Cameron again introduced the subject by showing some large-sized negatives (portraits of the Poet Laureate and Sir John Herschel) which had become injured by the formation of an innumerable number of vermicular cracks; and in the discussion which followed some valuable observations were recorded, particularly the use of paper wrappers for protecting the negatives, instead of storing them in the ordinary plate-boxes. Evidence was then given by Mr. Thomas, Mr. F. C. Eliot, and Mr. Hooper, in favour of this recommendation, which had since been amply endorsed by the experience of Mr. Jabez Hughes, Mr. Foxlee, and others. Mr. T. R. Williams was, two years ago, in the habit of keeping his negatives in plate-boxes; but these were always stored in a warm room, and kept away from the outer walls. Mr. Gordon had been particularly fortunate in escaping this kind of injury; and his success was probably due to the care with which his negatives were preserved in a cabinet placed in one of the warmest rooms of his house. It could not be doubted that the greatest enemies to the safe preservation of negatives were insufficient washing and exposure to cold and damp. The severity of the past winter, and abnormal fluctuations of temperature occurring within this period, seemed to have been the proximate cause of many disasters which had come to his knowledge. He had received intelligence from various quarters of injuries to negatives amounting

* See PHOTOGRAPHIC NEWS, Vol. VIII.

in the aggregate to upwards of 200 plates. Some of these might be due to insufficient washing, or to the use of impure water containing deliquescent chlorides; but many failures appeared to be attributable to an imperfect appreciation of the dangers arising from bad storage; and it was to be hoped that these past experiences would serve as a warning, and suggest the adoption of better precautions in the care of negatives for the future. A very striking illustration of the effects of severe atmospheric influences upon varnished surfaces might now be seen in the tablets of "Rules and Bye-laws" displayed at the Canbury and Highbury Stations of the North London Railway. These printed notices were of paper pasted upon iron plates and varnished in front; and whilst they exhibited on a grand scale the vermicular markings with which photographers were familiar, other tablets placed close beside them, but of millboard, had not suffered any injury to their varnished surfaces. The difference observed might be accounted for by assuming that there was an outlet for the escape of water by evaporation in the latter case, but not in the former, which approached the conditions of, and was much in the same state as, a varnished photographic negative.

In the course of last year the Berlin Society had appointed a Commission for the special examination of this question, and of the varnishes which appeared most suitable for the protection of negatives. The Report, as printed in Dr. Vogel's *Mittheilungen* of September last, might be summed up as follows:—

1. The use of a not too highly polished quality of glass, the Rhenish manufacture, for this reason, being preferred.
2. The application of a clear aqueous solution of yellow dextrine (one part of dextrine to eight of water) to serve as a preliminary coating especially suitable for retouching, if desired. The use of gum-arabic was condemned.
3. The temperature of 40° Reaumur (122° Fahrenheit) was not to be exceeded in drying the collodion film and varnishing the plates.
4. The use of alcohol of not less than 86 per cent. as a solvent in the preparation of the varnish.
5. The gums most suitable were found to be a mixture of mastic with orange shellac (avoiding the use of the bleached white lac), and the addition of a little boiled oil to make them tougher and more elastic.
6. Amber-varnish (solution in chloroform) might be used instead of dextrine as a preliminary coating, but could not be depended upon for giving by itself a varnished film of the requisite degree of hardness.

A valuable suggestion had also been given by H. Kruger, of Schwerin, in a paper "On the Splitting of Varnished Films; its Cause and Prevention," published in *Licht* of November last. The author recommended the addition of a small proportion of castor oil (which was freely soluble in alcohol) to the lac or sandrac used in making the varnish, and stated that by its use the brittle character of these gum-resins was entirely overcome, and a surface especially suitable for retouching secured. M. Kruger preferred a varnish made by dissolving one ounce of sandrac in eight ounces of alcohol, to which was to be added, after filtration, one drachm of castor oil. Negatives so varnished were said to bear exposure to sun and rain for many weeks without injury; no information, however, was given as to the possibility of being affected by frost; but there was every reason to anticipate a great degree of protection from the use of such a varnish.

Talk in the Studio.

HELIOGRAPHY.—On Thursday, the 16th instant, an interesting lecture on *Helio-graphy* was delivered by the inventor, Mr. Ernest Edwards, B.A., before the members of the Society for the Encouragement of the Fine Arts, in the Architectural Gallery, Conduit Street. The lecture was illustrated by a large number of fine examples of the process, in which the audience were much interested.

LANDSCAPE WORK.—We have been favoured by Mr. C. A. Fernely, of Melton Mowbray, with some pretty views in Bradgate Park, near Leicester. This place, which contains much good scenery, was the birthplace of Lady Jane Grey. It seems to offer many attractions to the photographic tourist, being easily accessible from Leicester, the distance being six miles

and, as our correspondent adds, there is a capital little inn within a quarter of a mile of the park.

BALLOON POST LETTERS.—Messrs. Letts and Son have issued, as mementoes of the war, lithographic facsimiles of a balloon post received in London during the early days of the siege. The letter is an interesting one in itself, and rendered more so as a complete facsimile, even to the stamps with the republican head, of the most eventful period of this century. We may here add that the same firm has sent us examples of a new well penholder, which permits any steel pen to take up and retain without inconvenience sufficient ink to write a letter covering four sides of paper. To persons having much writing this is a real boon.

INDECENT PHOTOGRAPHS.—At the March adjourned sessions at Clerkenwell, William Henry Payne, 41, Alfred Gollop, 29, William Miller, 27, Edwin Dresch, 21, and George White, 16, either pleaded guilty or were convicted of selling indecent books, photographs, and pictures. Sir W. Bodkin said the Court had hoped to put a stop to this disgusting traffic, but it seemed to be too profitable. They could only use the power which the law gave them to punish severely those who were guilty participators in it. Miller and Gollop, who had been often cautioned, must be imprisoned and kept at hard labour for 18 months, Payne and Dresch for 12 months, and White for six months, and then pay a fine to the Queen of £20. The Society for the Suppression of Vice were entitled to the cordial thanks of the public for instituting these prosecutions.

RENDERING THE INVISIBLE VISIBLE.—In the recent eclipse expedition, an excellent photograph was taken of the corona which is seen streaming forth all round the sun during totality. On subsequent examination of this photograph, the image of the planet Venus has been discovered among its rays; and in this we have an example of the power of photography in representing objects which the eye has not seen and could not see. Another example has been recently described by Mr. C. F. Varley. He was making experiments by passing a current of electricity through a vacuum tube, the results of which were indicated by strong or faint touches of light about the poles. In one instance, although the experiment was carried on in a dark room, the light was so feeble that it could not be seen, and the operators doubted if the current were passing. But, at the same time, photography was at work, and in thirty minutes a very good picture was produced of what had taken place. This is a remarkable fact. Indeed, it borders on the wonderful that a phenomenon invisible to the human eye should have been, so to speak, seen by the photographic lens, and a record thereof taken by chemical agency. It is highly suggestive, and we may anticipate that it will be turned to good account by practical philosophers.—*Chambers' Journal*.

BOTTLED HEAT.—A singular discovery is announced by the *Echo Rochelais* as having been made by a French professor at the College of Saintes, in Charente Inferieure. It consists of the singular fact of actually bottling the sun's rays and utilizing them at pleasure. The writer describes the operation as follows:—"The professor takes a vase—the material is not mentioned—and exposes it in a certain position to the direct action of the sun's rays. After it has thus absorbed the heat for the space of a quarter of an hour, it is closed with a cork and hermetically sealed, a small aperture being left in the cork. Affixing a powerful lens to the vase, he causes the solar rays to converge to a point upon the wick of a common candle, placed on a table at a distance of one yard from the vase. In less than three seconds the wick ignites and lights the candle, which burns steadily." The writer states that the experiment was tried several times, and was equally successful on each occasion.

TESTING THE GENUINENESS OF SILVER PLATING ON METALS.—Dr. Bottger says:—"A cold saturated solution of bichromate of potassa in nitric acid (sp. gr. 1.2) is taken, and applied to the metallic surface to be tested, after having been previously cleaned with strong alcohol, in order to remove dirt, fatty matter, and especially any varnish. A drop of the test fluid is then applied to the metallic surface by means of a glass rod, and immediately afterwards washed off with some cold water. If pure silver is present (as regards silver coins, these are left in contact with the test fluid for a greater length of time) there will appear clearly a blood-red coloured mark (chromate of silver). Upon German silver the test liquid appears brown, but after washing with water the blood-red

coloured mark does not appear; the so-called Britannia-metal is coloured black; on platinum no action is visible; metallic surfaces coated with an amalgam of mercury yield a reddish speck, which, however, is entirely washed off by water; on lead and bismuth the test liquid forms a yellow coloured precipitate; zinc and tin are both strongly acted upon by this test liquid, which, as regards the former metal, is entirely removed by water, while, as regards the latter, the test liquid is coloured brownish, and addition of water produces a yellow precipitate, which somewhat adheres to the fin.—*Chemical News.*

To Correspondents.

D. R. EVEREST.—We believe that Mr. Solomon, of Red Lion Square, keeps studio accessories made of composition or *carton pierre*.

GILCHRIST.—The tendency of acid additions to collodion is to destroy limpidity, and produce a gelatinous condition. The tendency of water is similar. Hence, if your collodion was originally made with spirits containing a full proportion of water, then a very slight addition of water with the nitrate of silver would produce this result. Unless the collodion be made with anhydrous solvents, we prefer to dissolve the silver salt in the collodion, as recently recommended by Dr. Liesegang. 2. The tendency of gold toning, when applied to collodion prints, is to bleach; and, if acid, to slightly destroy the finer half-tones around the high lights. The remedy consists in using the gold solution neutral, and in allowing for the bleaching in development. The mercury toning is very untrustworthy. 3. Your card lens will serve for enlarging well.

ANATOLE PERSIGNY.—The yellow spots on the cartes hung in your studio are examples of one of the forms of fading to which, unfortunately, silver prints are liable, which the damp and saline atmosphere probably tends to hasten. Great care in the production of the prints, and care in keeping them in a dry and pure atmosphere, are the only preventive means we know. Any carelessness in the original production of the print, in either fixing or washing, or any impurity in the mounting material, shows sooner or later, either in the form of yellow spots, or general discolouration and fading.

DOCTOR.—It is illegal to make any kind of copy from a copyright picture. 2. To prevent cards from curling after mounting, damp the cards previous to applying the pasted print. Also place them under a weight immediately after mounting, and allow them to dry under it.

A. BELL.—It appears that the necessities of your position compel you to adopt the proportions and general arrangements you describe, hence there is little room for suggestion or modification. But you must be fully prepared for endless trouble in making your principal light facing the south, on account of the constantly changing conditions of sunshine and shade. The length, 28 feet, is good; two or three extra feet in width would be an advantage if you could get it. The amount of glass is very good, and, if you could have had it on the north side, it would have been admirable. 2. The Salomon above background will aid you materially, but only experience will determine whether, in such a room, it will need to be supplemented by blinds. 3. Any quiet neutral tint of a grey character will answer for the interior. 4. Rollers for the blinds are better placed at the ridge than the eaves. 5. Let the panes have a good overlap and sufficient pitch, and they will not leak.

ELWOOD TERRY.—There are no medals at the American Exhibition. So far as we know, the contributions to the last Paris Exhibition are in Paris still. The sudden opening of the war closed the exhibition, and the specimens were hastily thrust aside, as the room was required for another purpose. We have never heard details of the fate of the pictures.

MARS.—The fact that the print forwarded is saturated with wax or varnish of some kind modifies the colour somewhat, but the chief cause of its tendency to drab instead of a definite black, purple, or brown, is probably due to the character of the negative, which seems to be somewhat weak. When a negative is too weak to permit vigorous and deep printing, the print retains a drab tint if a warm tone be aimed at, and soon runs to a slate tint if black be aimed at. 2. We do not quite understand your question as to a method of burning-in by heating metal. 3. We have but little experience with drying-boxes suited for carbon tissue. Local circumstances must determine the best method of applying heat. A double perforated top, with the perforations not coincident, will be necessary to permit the egress of moisture, but, at the same time, exclude light.

PYRO.—We scarcely understand what you mean by a black granular deposit. Is it fog? Or is it a coarse metallic image? Pyrogallic acid generally produces a finer and less crystalline looking deposit than iron.

SPOTS.—The mottled, irregular colour your cards assume in printing is due to irregular and imperfect sensitizing of the paper. Your printing bath is getting somewhat weak, and you have had a small quantity only in the dish. Possibly, also, the dish was not standing level, so that a very small portion of solution indeed was under that portion of the paper where the mottling chiefly occurs. At any rate, you will find that by strengthening your solution, and using a greater quantity in the dish, you will avoid this irregularity. It is well, also, to agitate the solution after sensitizing a few sheets, because the silver, being rapidly abstracted from the top layer, agitation is necessary to equalize the strength. 2. You will find the mode of adding alum described in an article by Mr. Anthony in a recent number. 3. The addition of a little sugar or gelatine to the developer increases intensity. You will find many recipes for such developers in our *YEAR-BOOKS*; but the question of whether a negative will need intensifying is as much dependent on collodion, lighting, and manipulations as on the developer.

T. S. REEVES.—We will bear the matter in mind.

E. J.—An ordinary boiler will not serve to boil down a bath in. A porcelain evaporating dish is the proper thing. 2. The chief cause of pinholes is supersaturation with iodide of silver. 3. It is safer to use recrystallized nitrate of silver for a negative bath. 4. You can only sue the person. But this is a question upon which a lawyer can best advise you.

E. D.—The proper course is to obtain from Stationers' Hall some blank forms, which require properly filling up with the title and other particulars relating to the photograph. These must be personally deposited at Stationers' Hall, and one shilling paid with each. If you send stamps to our publisher he will get you some forms, and if you then fill them up and return them to him with one shilling and sixpence each, he will personally superintend the entry.

DANE.—As a rule, where acetic acid is mentioned in formulæ, glacial acetic acid is meant. In the 15-grain iron solution you mention, for instance, glacial acetic acid is intended. Glacial acetic acid is said to be solid at 60°, but, as a rule, you will find it liquefy at a temperature over 50°.

BELMONT.—Your negatives arrived broken; but we find a piece of the background sufficiently large in each to show a cloudy irregular transparent mark, which appears to us to be caused by the pouring on of the developer, which is sometimes a cause of such marks. The remedy consists in pouring on the solution gently with a sweeping motion, and also to use the developer freshly made. The portrait of the child is pretty. You want a more efficient means of masking, so as to secure sharp perfect edges to your oval.

W. W.—As a rule, you may keep a gold solution neutralized with carbonate of lime safely, provided it be kept in the dark. We generally keep a concentrated gold solution in alcohol, in which case, although quite neutral, there is no risk of decomposition or precipitation of the gold. The solution not turning blue litmus red is fair test of its neutrality; but in neutralizing with carbonate of lime there is little danger of adding more than will neutralize the acid present, as it is not soluble in water.

F. STONE.—Acetate and citrate of ammonia may be made by neutralizing carbonate of ammonia by means of acetic acid and citric acid. 2. Unless you mention a specific formula in which they are used, we cannot very well tell you the purpose they are intended to serve. The action of acetate of ammonia in the toning bath would be similar to that of acetate of soda, and we see no object in substituting the ammonia salt for the soda salt. The action of citrate of ammonia in the silver bath would be to precipitate a little of the silver in the form of a citrate. It would remove the brownness from a discoloured bath.

J. GIRAULT.—By thirty drops thirty minims are meant. The use of the term "drops" is inexact, as drops of different liquids vary in size; but it is a somewhat common error in this country to use drops in place of minims. 2. The combining weight of strontium is 43.8, and that of calcium 20, so that in a grain of chloride of calcium there is really twice as much chlorine as in a grain of chloride of strontium; half the quantity, therefore, will be required.

AMATEUR.—Your question is not sufficiently definite. You ask for instructions in "the process of heliotype to produce a gelatinous positive to transfer to stone for lithographic printing." Heliotype and photolithography are two distinct processes; but we have repeatedly described both. You will find details of the heliotype process, which it is we think you want, in our last volume, and also on p. 101 of our last *YEAR-BOOK*.

M. B.—We regret that we do not know of any firm which undertakes carbon printing from the negatives of others, now that the Autotype Company have given up that branch.

J. WADE.—Thanks. We will make use of the paragraph.

R. TUDOR WILLIAMS.—Received. Many thanks.

Several Correspondents in our next.

THE AMERICAN PHOTOGRAPHIC EXHIBITION.

We have pleasure in announcing to intending contributors to the exhibition to be held in Philadelphia, in connection with the meeting of the American National Photographic Association, that arrangements have been made whereby they will be relieved of much trouble and expense. Instead of packing their cases to stand a voyage, and paying the freight, they will simply have to pack their frames in ordinary cases, and forward them to Messrs. Joseph Green and Co., the well known fine-art packers, 14, Charles Street, Middlesex Hospital, who will provide a proper case for the voyage, and despatch the whole together. The National Photographic Association will pay the freight in America, and the only charges which the exhibitors will incur will be that of transmitting to Messrs. Green and Co., and the share of cost of packing. The sooner the cases are forwarded for packing the better, and none should reach the packers later than April 8th. When the whole are received, Messrs. Green and Co. will inform each contributor of the amount of his share of the packing, and this must be paid at once, as no picture will be packed or sent until the share of the packing is paid for, and Messrs. Green must despatch the case by April 14th. Each package sent should have the sender's name and address outside, and an intimation that it is for the American Photographic exhibition. It would be well, also, to send a note to Messrs. Green at the same time, notifying them of the matter. The proper communication must also be sent to Mr. Wilsou, in Philadelphia, as before announced. We trust that these increased facilities will increase the number of contributions, and that all English photographers who have good pictures to send will aid in maintaining the honour of their country, and gratify their American brethren by aiding in securing a good display of the photography of the world in the exhibition to be opened in Philadelphia next June.

CRACKED NEGATIVES: RENTS, RIDGES, AND RUPTURES.

The deep interest evinced in the recent discussion of this question, fully as it has been ventilated before, strikingly illustrated the wide-spread prevalence of the evil, and the uncertainty still existing as to both causes and remedy. Unfortunately, the value of the discussion was slightly marred by the presence of a little confusion as to the terminology employed. In all discussions, it is of vital importance to commence by defining terms. Mr. Rejlander evidently recognized this necessity, and divided the two classes of disruption to which the negative film is subject, as *cracking* and *splitting*; and if the distinction had been fully recognized and observed, the terms would have served as well as any other. Unfortunately, however, they did not seem to be recognized

as sufficiently descriptive, and hence they began to be confounded with each other, and used indifferently for either form of defect.

Those who are familiar with this most dire of the defects to which negatives are subject, know that the two forms of cracking of the film are quite distinct in character; and, whatever may be their remote source, their proximate causes are directly opposite to each other. As Mr. Hughes very clearly put the case, one series of cracks is evidently caused by contraction of the film; it is torn asunder, leaving fine transparent lines between, which run over the plate in an excentric net-work. The other series of cracks is clearly caused by expansion of the film, which first rises up in honeycomb-like ridges, causing an intermediate form of evil, and, eventually being disrupted, these ridges form wide cracks beyond redemption or cure. These two terms (*contraction* and *expansion*) describe accurately both immediate causes and result, but they are too cumbersome for general use as descriptive or distinctive terms. We propose terms which, whilst sufficiently distinctive, and not easily confounded, are sufficiently terse and expressive for general use. We shall call the two—or, rather, three—forms of evil, *rents*, *ridges*, and *ruptures*. The *rent* consists in an actually splitting or tearing asunder of the film by contraction; the *ridge*, as will at once be understood, is the result of expansion, the film rising in ridges at times like honeycomb cells, and at other times running over the plate like the branches of a tree; the *rupture* is caused by the breaking of the ridge, leaving a wide opening in the film. These terms are sufficiently descriptive and distinctive, we think, to clearly indicate each form of the evil in question.

The discussion at the Photographic Society threw some light on the question, although it left much in obscurity. The cause of the fine, hair-like *rents* in the film is least understood. The suggestion of Mr. Blanchard, that they are generally due to the use of a special contractile collodion, seems to present the most probable solution. His conviction was, that they occur in a collision with well known characteristics, which we may here repeat. It sets rapidly when poured on the plate, giving a glossy and horny film; is often a very sensitive, excellent collodion, and shows, in the finished negative, a tendency to pull away from the edges of the glass. Most photographers are familiar with this quality of collodion, and, as it generally yields a good negative, it is often a favourite. But if it have an especial liability to this splitting tendency, it is evident it should be shunned. It becomes important, however, that the facts should be verified, and that the characteristics which indicate the special class of collodion should be well defined; and, as the testing process of time and wear cannot be readily and efficiently anticipated by improvised tests, the investigation must necessarily be slow and tedious.

Fortunately, a tolerably simple and effective remedy for

this form of the evil exists. The fine cracks or fissures in the film, which, of course, print as black lines, are easily filled up by rubbing the film with a tuft of cotton charged with finely powdered plumbago or carbon, or, as Mr. England finds better still, with Indian ink rubbed up with a little water. At first sight it would seem as if the material rubbed into the fissures in this way must inevitably make opaque lines in the transparent parts of the negative, which, printing as fine white lines, would require touching out in the print. But this is not so: the fissures in the more transparent parts of the negative are very shallow, and when filled up with carbon are only of an equal density with the surrounding semi-transparent parts; whilst the fissures in dense parts of the negative, being deeper, take a thicker layer of the carbon to fill them up, and this thicker layer gives a density corresponding to that of the part in which the rent or fissure occurs.

The cause of the *ridges* was clearly traced to damp, or, rather, to transitions from dry to damp conditions, and, further, to confinement in boxes under those circumstances. Mr. Frank God having recently moved from a dry residence to a very damp one, found his negatives rapidly going to destruction in the ridge-form defect. Moving the negatives from the boxes in which they had been carefully kept, wrapping them in paper, and placing them in open pigeon-holes, at once arrested the destructive process. Mr. Hughes related an instance in which a box of negatives in good condition were placed in a studio beside a stove, where they got hot; a cold, damp night followed, and in the morning they were all covered with honeycomb ridges. A case we heard of at the close of the meeting was more striking still. An operator called at a printing establishment for a valuable negative which had been given out to print, and, according to instructions, he examined it to find that it was in perfect condition. It was, when he received it, still warm, having recently been printed by the electric light. He wrapped it carefully up, and took it to his employer, who opened the parcel at once to see that the negative was uninjured, and, to his horror, found it covered with the honeycomb ridges. This had occurred during the half hour the parcel was carried in the street during a damp day.

But whilst damp and transition of temperature seem undoubtedly to constitute the proximate cause of the honeycomb and arborescent ridges, there a.c. we think, predisposing causes to be considered. Not all the negatives in the same batch will suffer when subjected to the same damp and transitional conditions, and there must be a cause for the difference. A very curious example of the exceptional occurrence of the ridges came within our own experience. Some winters ago, in the course of some experiments, we were desirous of working with a variety of negatives of different qualities and characteristics, and so borrowed some of two or three friends. The room in use as a printing room is a somewhat damp one, and some scores of negatives stand on shelves in it without any especial protection. We have never had a single negative cracked of our own, nor, despite the exposure, did those of our friends crack except in one instance. One morning we found one, and one only, covered with honeycomb ridges. There were at least a dozen negatives by the same gentleman—a singularly neat and careful amateur—and scores by others, all kept in the same conditions; but one only was injured. It is clear, then, that some predisposing conditions existed in that negative which were absent in the others. Whether these conditions arose out of the quality of the collodion, the quality of the varnish, or imperfect washing of the film, we cannot with certainty say.

The remedy for the ridge form defect, if taken before the ridges have become ruptured, is simple. It was first proposed in our pages (p 81 Vol VII) by Mr. Nichols, and subsequently verified by Mr. Spiller, who describes his operations also in our pages. The remedy consists in submitting the injured negative to the vapour of alcohol, which

causes the complete disappearance of the defects. Mr. Whiting has got rid of similar defects by simply re-varnishing.

The general impression with many photographers is, that in most cases of cracking the varnish is chiefly in fault. Certain it is that varnished pictures often crack in the same way, and that an unvarnished negative has never been known to crack. Hard friable varnishes sometimes crack when applied on the surface of glass only: witness the black varnish which used to be applied to the backs of glass positives, and which frequently cracked. Copal is known to have an especial tendency to crack, as may be seen at times on paintings and coach panels. Mastic, on the other hand, and similar resins, rarely, if ever, crack; but these are an insufficient protection to a negative. Lac is not given to cracking; we never saw a French-polished surface cracked, nor any Japanese lacquer work. As a rule, no matter what the tendency of the varnish itself, cracking rarely occurs without some want of harmony between the varnish and the surface to which it is applied. If a painting be varnished within a few months after it is finished, it will almost certainly crack. Exposure to the direct action of the sun will cause many varnishes to crack, and hence it may be that direct sun-printing is injurious.

The preventives which the discussion at the Society suggested seem to be the use of collodion which is not too contractile and horny; the avoidance of damp, and especially of sudden transitions of atmospheric conditions; the storing of negatives wrapped in paper in open pigeon-holes, rather than in boxes; the cleaning of the face of the negative, and covering it with a paste of wax and turpentine when put away. To these we may add the careful use of clean plates; full exposure, so as to avoid forcing in development; the use of varnish with a few drops of castor oil in it; the avoidance of varnishes containing copal and similar resins; and the avoidance, as far as possible, of direct sun-printing.

LIABILITY OF PHOTOGRAPHERS FOR INJURY TO PHOTOGRAPHS LEFT IN THEIR HANDS TO COPY.

A QUESTION of somewhat vital interest to professional photographers has recently been brought under our attention by Mr. Ernest Edwards. The question is, to what extent is a photographer responsible for the safety of objects left in his hands to copy? A recent County Court decision seems to render him responsible to a degree certainly not commonly imagined. By this decision, he is rendered liable, not simply for the actual value of a photograph left to be copied, but for the expense of replacing it by something superior, and much more costly, obtained at the caprice of the owner. We will quote Mr. Edwards' narrative:—

MY DEAR SIR,—I have had a county court experience which, I think, will interest photographers.

Some years since I photographed for Miss Eyre a *cast* (note this) of a bust of her brother Sir James Eyre, at a cost of 10s., and supplied her with at least nine copies. At the end of last year Miss Eyre required another copy, but the negative had, in the meantime, been crased. An agreement was made that she should supply us with one of the original copies, which we were then to re-copy, and a proof was to be supplied to her for 5s. Unfortunately, an accident happened to this copy supplied by her. I wrote to her, expressing my regret, but intimating that if another copy were lent, it (the destroyed copy) should be replaced, and the additional copy she required supplied, all without charge. She intimated, then, that she had not another copy, and should not lend it if she had; but that she should send down to Hereford where the bust itself (not the cast) is placed in the Town Hall, and have it photographed at my expense. Accordingly, after a time, I was sued in the Marylebone County Court for £1 5s. 6s. paid by her. I contended that I had taken every reasonable care, that no negligence was shown, that at least it was only a question of a shilling for actual damage, which was the value of the photograph des-

troys; then that I could not be called on to pay more than 5s., the agreed price for the additional copy, and that, to obtain this, she only had to take another copy to another photographer if she would not entrust it to me, to which she swore she had never had more than one copy, so that was impossible. I then contended that she should have gone to the *cast* which I had photographed, which was still with the sculptor in the Euston Road, and not to the bust itself, whereby she obtained a better article than that destroyed; and, finally, I pleaded the custom of the trade: that it was always understood, in such cases, photographers were responsible only where negligence could be shown, and not in case of accident.

To this Miss Eyre pleaded that Mr. Kidd, to whom she had given the order, undertook to be responsible. However, the judge, throughout, would hardly listen to the defence, distinctly saying, in such a case, he should not regard the custom of the trade, and gave the plaintiff a verdict amounting, with costs, to £1 18s. 3d.

I found, however, that the barristers and solicitors in court expressed such a very strong opinion that the judge was wrong that I determined on applying for a new trial.

On a subsequent day this application was made, on the ground of the absence of Mr. Kidd, and that my books would show that a number of copies had been supplied, and a new trial was granted, which came on last Wednesday. Mr. Kidd then proved that he had distinctly guarded himself against being responsible; that he had only undertaken every possible care; and my books proved the sale to Miss Eyre of nine copies of the original negative. Otherwise, the same arguments and the same evidence was given, and the same result followed: a verdict for the plaintiff for the full amount claimed, with costs.

I may as well say that I had informally taken counsel's opinion from a friend, a barrister of high standing, who said decidedly nothing could be recovered beyond a shilling, the value of the photograph destroyed. This friend was in the court during the hearing, and his opinion remained as before: that the judge was wrong.

It seems to me that this is a very important matter for us. By this decision, if any trumpety article entrusted to us is destroyed, whether by accident or negligence—whether negligence is proved or not—we are liable to the cost of replacing it at any expense at the mercy of the owner, if that owner chooses to send to the ends of the world to do so. And the glory of the County Court is, that there is no appeal against such a decision, which, therefore, establishes a precedent.

For ourselves, we can only say *experto crede*. We shall take care, in such cases, to have a written understanding that we will only be responsible in case of negligence, and for intrinsic value.

I hope you will agree with me, that it will be well to publish this matter of experience for the benefit of others.—Yours very truly,
ERNEST EDWARDS.

The soundness of the law in the decision we cannot pretend to determine. One of the greatest legal commentators defines law to be "the perfection of reason," and, if the definition be good, few people will have much hesitation in styling the law in question as bad; but, at any rate, it behoves photographers to have a proper understanding with crotchety customers as to the amount of liability they undertake when objects are entrusted to their care for purpose of copying.

Critical Notices.

PHOTOGRAPHIC MOSAICS: an Annual Record of Photographic Progress for 1871. Edited by E. L. WILSON. (Philadelphia: Bennerman and Wilson.)

PHOTOGRAPHISCHES JAHRBUCH für 1871. Herausgegeben von der Redaction der Photographischen Correspondenz. (Vienna: Dr. Hornig.)

Our readers are familiar with Mr. Wilson's *Mosaics* of former years through the quotations which have appeared from time to time in our pages. If possible, this year's issue exceeds in excellence any which has preceded it. Besides a most judicious selection of the most valuable and practical papers which have appeared in the journals during

the year, it contains an admirable array of original articles by the most able practical men in the States, on subjects to which they have given special attention, and upon which they can speak with authority. Altogether, the work is one upon which we can heartily congratulate our friend Mr. Wilson and his readers: as reflecting the highest credit on one, and possessing the highest possible value to the others.

Dr. Hornig's *Jahrbuch* is another of the valuable little photographic annuals which it was our good fortune to initiate nearly a dozen years ago, and which, we note with pleasure, have become recognized necessities in the photographer's studio all over the world since then. The *Jahrbuch* chiefly devotes itself to condensed information for reference, in the form of a pocket-book, and contains space for memoranda. It is illustrated with a fine specimen of Lichtdruck by Julius Leth.

SIGN WRITING AND GLASS EMBOSsing: A Complete Practical Illustrated Manual of the Art. By JAMES CALLINGHAM. (London: Simpkin, Marshall, and Co.)

We have rarely met with a book so inadequately represented by its title as the valuable volume before us. It is undoubtedly a complete practical manual of the arts of which it treats, but it is also much more. It is a complete history of the various forms of written and printed characters used in the English language, and a treatise upon their varied possibilities of shape and design as a branch of decorative art, written with a fullness of knowledge, and a thoroughness of relish and appreciation of the subjects, which never fails to give a peculiar charm to any volume. The work is one which possesses so many points of interest to any interested in the graphic arts, that we should feel pleasure on that ground alone in commending it to the attention of our readers; but besides this, they will find in the chapters on glass embossing and gilding many details and suggestions of a technical character, which may possibly be utilized in their own practice.

RETOUCHING NEGATIVES.

We have before us a little work—published in the United States at a dollar and a half, equivalent to about six shillings—on retouching negatives and positives. It is by John Wolfgang Morgeneier, who addresses it to the "artists of the world," and states that the book has cost him many years of labour and experiment, and that he is assured that it is "superior to anything yet before the artistic world." As the instructions are comprised in about half a dozen small pages, and the book is not published in this country, we propose to place them before our readers. After describing the virtues of a matt varnish, which the author has invented, but the preparation of which is not described, the work proceeds as follows:—

Negative Retouching (Contact).—In order to retouch a negative properly and speedily, it is only necessary to procure a retouching frame, which can be procured at any photographic stock house. The materials used by me for retouching are, one box of Faber's polygrade lead pencils, from No. 1 to No. 7, one middling sized, round camel's hair brush, used for brushing off superfluous lead during the operation, two small pointed camel's hair brushes for applying indian ink and dry colours, and one two and a half inch magnifying glass. Secure the negative in the frame, place opposite a window and exclude all or as much light as possible, from the sides and overhead, leaving only the light showing from the window on the negative. The reason why the light must be excluded from sides and top is, because the negative presents a ground surface, and should the light reflect the face, the lights and shades could not be so readily discerned. The negative must be covered with a piece of dark-coloured soft paper, with a hole cut in large enough to show the head of the portrait that is to be retouched; the

purpose is to preserve the negative and cut off superfluous light. After retouching the face of the portrait, the paper may be removed to retouch any imperfections in the drapery or background. The polygrade pencils used have such a degree of grades that you can produce any light or shade desired. The retouching can be done either by stippling or sketching, or both. In retouching the drapery, I often apply the dry ambrotype colours, to wit: light blue, white, purple, &c. The application of dry colours should be very light, as it adheres to the varnish, and can easily be made to show a dauby thick appearance. If any part of the negative should be retouched too intense, it can readily be removed with a soft, round, camel's hair brush, dipped in rain-water, without injuring the film. Ever since the foundation of the photographic art there have been objections made in regard to pictures, objections founded upon the imperfect working of chemicals; this difficulty has now been overcome by this new retouching process, which enables the artist to remove any imperfections arising, from whatever cause they may come, and thus enables him to give the public such improved work as will satisfy the most fastidious. The principal points in the features of the negative to be retouched are, the forehead, nose, eyes and surroundings, cheeks, mouth, jaw, chin, and neck. These points being properly retouched, modulating the lights and shades adds materially to the beauty of the photograph. This comprehends the matter of retouching the negative. At first I retouch away all specks and pinholes, or any imperfections in the negative, background, or portrait, which often occurs. After this, commence the features, one at a time; first the freckles, moles, warts, scars, &c., which being removed is sufficient to give satisfaction in almost every case, excepting in very old or middle aged persons. I wish now to call the artist's attention to the following instructions in retouching negatives:—

Forehead, No. 1.—The upper and lower forehead being the principal features of the face of the portrait, invariably takes plain, excepting the wrinkles immediately over the eyes and on the lower forehead, which must be retouched so as to smooth down; not, however, entirely removing them, as that would mar the natural appearance of the portrait. But the cross wrinkles running up and down the forehead greatly mar the beauty of the picture, and may be entirely removed, excepting the two principal ones running directly up between the eyebrows, which should be only slightly retouched. The eyebrows, although different in all persons, invariably follow the course of the eye, and should they be large and bushy, they must be retouched so as to make them appear smooth, encircling the eye properly. Should the eyebrows meet upon the forehead, as they often do, they must be entirely retouched away, as they will, if left, give the expression a surly appearance. The natural shade between the eyes only need remain, as that will be sufficient to make a natural appearance. The above instructions must be followed more or less according to the age or sex of the subject. In a profile or a side view position of a portrait, if there is an over-abundance and a superfluous amount of hair about the head, or an excess of drapery, it can be readily retouched away, or should deficiencies appear they can as easily be added. Blonde hair, which usually takes dark, can be lighted by sketching with the pencil on the negative. Dark beards, or any other under-exposed colours of hair, may be treated in like manner.

The Nose, No. 2.—The nose runs parallel with the face, and presents a flat, sharp, or rounded appearance. The ridge of the nose should always be retouched, simply by drawing a line along the same to part the ridge from the side of the nose. In persons who have Roman noses a dark shade appears on each side, which should be retouched enough to soften the shades; this will appear more especially in dark brunette or sunburnt complexions, and they may be retouched to a higher or lower degree without injuring the expression. The shades can be reduced should they appear too dark. In a front face or profile position crooked

noses may be very much improved in this manner: the shades of the nostrils should not be absolutely dark, and the shade of the point of the nose should not be as dark as those of the nostrils. Intensifying the point of the nose with the pencil gives it a classical appearance. In the profile of the nose the ridge should never be retouched, as it will change the whole expression of the face.

The Eyes, No. 3.—The eye is one of the most important parts of the portrait, and especial care should be taken in posing the subject in order to give the eye a natural appearance or expression. After all the care that can be taken, the helping hand of the retouching operator will be necessary to perfect the work in almost every instance. I will describe several points of special importance. By exposure the usual sharp glance or clear look of the eye becomes dim, the lids and pupils become blurred or hazy; this can be relieved by retouching the *Iris* of the eye, and by subsiding the high lights in the pupil. It often occurs that the high lights in the shaded eye are stronger than those of the light shaded one; it should be retouched so as to perfectly correspond. Blue or very light coloured eyes often take almost white. To procure a nice, natural appearance, it is only necessary to pierce a small hole in the sight of the eye, using a sharp steel needle, and requiring but a moment of time, and is easily performed on the negative. This is especially necessary in small photographs. The veins in the white of the eye of aged persons will show to a certain extent, especially in large prints, and should be entirely removed, but the white should not be retouched. The projection of the forehead immediately between the eye and the eyebrow usually takes too dark, and should be retouched enough to give it a soft shade. The so-called fleshy under-eyelids, producing dark and unharmonious shades under the eyes, should be retouched considerably. In aged persons the cross wrinkles in the fleshy under-lid should be entirely removed; by retouching in the manner described the eyes are greatly improved, and the features or look of age remains unchanged. The crow-foot wrinkles running from the corners of the eyes are very characteristic, and should not be entirely removed.

The Cheeks, No. 4.—The dark shades upon the back part of the cheeks where it meets upon the forehead should be retouched so as to blend the two together in harmony. Retouch the dark shades of thin, sunken cheeks, which show leanness and homeliness, so as to make the cheeks appear full, giving a pleasant expression. Negatives taken from brunette subjects require more intense retouching.

The Chin, No. 5.—In corpulent subjects the chin shows a double form, appearing as part of the neck, giving it an unnatural appearance. A part of the double chin can, or should be, retouched, so as to make it appear as part of the neck, which can be done by retouching away one or more of the small wrinkles under the natural chin, thus improving the appearance of the chin very much. The dimple of the chin should be softened, as it often appears as a cut or dark spot. It will be necessary to retouch the full, fleshy portion of the face more than any other. The shades of the neck immediately under the chin should connect with the shade of the chin. The rough or corded appearance of the neck caused by the showing of large wrinkles or veins should be carefully retouched away.

The Mouth, No. 6.—The mouth through the easy motion of the raising up or down of the corners, is the principal sign of intense emotion, and this can be changed without trouble. The form of the mouth may be easily and very much changed or improved by drawing and retouching the outlines of the lips. Retouch away all the ugly-looking scars or wrinkles that appear on the lips. In aged persons the corners of the mouth run downward; these may be retouched so as to show with the outlines of the under lips in an even line. The upper lip in aged persons sinks inwards from the loss of the teeth, showing a dark shade above the upper lip, which, if unretouched, shows like an unshaven beard, but if retouched it gives the mouth a

natural expression. But care should be taken to retouch it in such a manner as not to change the natural expression between the nose and lip. The outlines of the lips are quite different; large, full lips being more exposed, produce a more harmonious effect than thin, close ones. In aged persons the corners of the mouth are apt to be drawn down, causing the mouth to seem long; this can be easily remedied by retouching so as to shorten their appearance, but the shades should not be entirely removed. Should the wrinkles turn up instead of down, they should not be retouched away as much as those running down, as the downward ones have a tendency to make the expression sorrowful or dejected. Should the subject have teeth that prevent the closing of the mouth, causing them to show, they may be retouched before varnishing the negative, using a small-pointed ambrotype brush, care being taken in stippling the intense spots, so as to harmonize with the shade of the lips.

The Drapery, No. 7.—I will now make some special descriptions of draperies, and give instruction in regard to retouching or changing to suit the taste. I have done, and am now doing, a great deal of retouching unvarnished negatives in the following manner: using only the common ambrotype brushes as aforesaid, flowers, ribbons, neckties, and other draperies that often take too intense can be changed or removed, according to taste, causing the drapery to show plainly and harmoniously, leaving the effect entirely with the artist. Should these directions and observations be followed, many gross imperfections may be removed from the negative, and many beauties added thereto, which can be easily done by any other process. Since the negative retouching process has been practised for some time back, and as it is gaining day by day, I think any artist, strictly obeying the instructions laid down in this little *Book*, and using my *Patent Varnish*, will be rewarded in the shortest space of time by entire success in his profession.

Foreign Miscellanea.

A NOVEL method of engaging the attention of children during the period of their being photographed is that of setting up a parrot, which, on the removal of the cover from the lens, commences to flap its wings.

Licht gives a recipe for a substitute for tunicare, to be applied to the plate previously to its being coated with collodion:—

Distilled water	2 ounces
Spirits of wine	1 ounce
Glacial acetic acid... ..	3 drops
White of one egg beaten to a froth.	

After allowing the solution to stand for a night, it is filtered, and mixed with three ounces of distilled water. This, it will be seen, is precisely the formula of one of our correspondents, which we published a few months ago.

In the *Correspondenz*, M. Schaarwachter gives the following receipt for preparing ink rollers suitable for Lichtdruck processes. Three parts of good brown glue are allowed to soak in cold water for two days, and are then melted over a slow fire, one part of boiled treacle being subsequently added, and the whole brought to the boiling point; the mixture is poured into a cylindrical mould of copper, of which the interior is greased, and in the centre of which runs the wooden handle. When cold, the roller is washed with spirit, dried in the open air, and finally immersed in a solution of tannic acid, and washed and dried. This resembles the ordinary printer's roller, and would, it is to be feared, pull too much for a printing surface of gelatine, and so risk its destruction.

The mechanical printing process of M. Obernetter, of Munich, is rapidly progressing. The grain noticeable, especially in the smaller productions, has been now completely done away with. A copy from one of Mieczkowski's negatives printed by this process will be given as a presen-

tation print with the next issue of the *Archiv*. Many of Obernetter's employes are just now engaged upon military service, and, therefore, operations have come almost to a standstill; but from one plate, a reproduction measuring some thirty by forty centimetres, as many as 40,000 copies have been struck off.

M. A. de Constant has made a statement to the effect that, as the final result of his experiments with light in the camera, he finds it best not to tamper with the blackened inside of his apparatus, but, instead, to introduce a red, or rather rose-coloured, light into his studio; this improves and softens the portraits.

A very perfect specimen of Albert's Lichtdruck process has been issued with the Dresden journal *Helios*. It is a bust portrait of a lady, and proves that very considerable progress has lately been made in the art.

M. Krone, of Dresden, has also perfected his Lichtdruck process, and exhibited copies of the same at a recent meeting of the Dresden Photographic Society.

Some discussion took place at the last meeting of the Berlin Photographic Society on the subject of gutta-percha baths used for photographic purposes. M. Kruger stated that he had examined analytically some pieces of a bath which had become quite brittle and rotten, and found the same to contain an appreciable quantity of silver.

The German photographers engaged in the recent war are making good use of their opportunities. M. Petsch is at Thionville, where he has secured some large photographs of the walls and fastnesses of the place; and MM. Schwier and Quidde are busily engaged in depicting the Paris forts from different points of view, as also in securing pictures of such spots around the capital which are of historical interest.

An art exhibition, to include photography, will be held at Dresden this year. Specimens must be forwarded to their destination not later than the 15th April.

The recent cold weather has yielded some experiences to photographers. The idea that a frozen silver bath cannot be subsequently employed after being thawed is proved to be erroneous. One observation worthy of note is the fact that upon the freezing of a gold toning bath the chloride separates at the top, and remains in a liquid condition.

M. Meuwssen, of Wipperfurth, has made trial of rose-coloured light for portraiture, in the manner suggested some time since by M. de Constant. He places the sitter in a recess illuminated by a glow of red light, by the aid of rose-coloured tissue-paper, which is stretched over a frame. The portraits thus produced are said to be very clear and soft.

No French photographic journals have been received from Paris since the siege. The back numbers of many of them—among which is the *Comptes Rendus*—are being rapidly printed and circulated. It has not been stated whether this course will be taken with the *Bulletin* and *Moniteur de la Photographie*.

The *Photographische Archiv* contains a suggestion with reference to the use of blue light in studios. Instead of employing blue glass for glazing the building, a saturated solution of Glauber salts in beer is used, to which as much Prussian blue is added as will secure the proper tint. The mixture is applied to the glass in a warm condition, and, on cooling, it crystallizes. If it is desired, at any time, to remove the tint—as, for instance, in winter, when there is great lack of illumination—the colour is easily rubbed from the glass surface by means of a wet sponge.

The subject of faded albuminized prints received considerable attention at a recent gathering of the Berlin Society. Some prints were exhibited which had been exposed for upwards of three years, in a show-case, to direct sunlight without showing any traces whatever of fading, thus proving that decay was more the cause of noxious vapours in the atmosphere than the action of the sun. Bad cardboard, or acid mounting materials, were cited as frequent causes of fading.

A paper on the reduction of chloride of silver by a

wet the metal is communicated to *Licht* by Dr. Gräger. Zinc is the method employed to effect the reduction.

The *Photographische Zeitung* calls attention to the employment of hydrate of chloral as a useful reducing agent, capable of employment by photographers for treatment of gold solutions. For waste silver solutions, its use is not recommended, as the production of chloride of silver ensues.

AMERICAN CORRESPONDENCE.

METHOD OF MOUNTING PRINTS—THE WOODBURY PROCESS IN AMERICA—RESTORING FADED PICTURES—VARNISHING THE NEGATIVE—TESTIMONIAL TO MR. NOTMAN—NEGATIVE RETOUCHING VARNISH.

Method of Mounting Prints—Here is another little practical idea which may be of service to those who have large pictures to mount. With our larger pictures are generally mounted on a card with an oval line lithographed in the centre, and the proper registration of the print, with the line, is sometimes difficult. Here is a means of overcoming the difficulty:—It consists of a plain board, ten by twelve inches (or any size you wish), with a flange (*a*) high enough to let under two card mounts, one of them fastened to the board, and the different square and oval patterns marked on it, at the right distance from the end (*b*), to suit the different sizes you have to mount, either square or oval.

Suppose we are mounting oval prints. (*b*) Is the print cut to the proper size, pasted, and laid face down on the oval pattern; now take the mount, slip it under the flange (*a*), to correspond with the pattern, and press it gradually down. Then pass the hand over the back a few times, and you have the print mounted perfectly true. Of course, it is of no use for anything smaller than a cabinet card, but I think if any one tries it for large prints they will like it.

The Woodbury Process in America.—The Woodbury process is now in successful operation in this country under the superintendence of Mr. J. Carbutt, and you have, no doubt, seen one of the first results in the picture in the first number of the *Photographic World*. The "works" are located at No. 1002, Arch Street, in the centre of our city, and every facility is secured for the successful working of the process. Let those who would try the process, however, beware of the hydrostatic presses "made specially for the process" in Paris. They are absolute trash. The one Mr. Carbutt got there burst without even making a decent mould. I will have more to say about the works here, and send you specimens soon.

Restoring Faded Pictures.—A photographer is very often called upon to reproduce old photographs which are not only badly faded, but which are of such a dingy yellow colour that they almost baffle him in his efforts to get anything like even a tolerable copy therefrom. The colour of the picture is even a worse drawback than the weakness of the image.

The matter was discussed at considerable length at the last meeting of the German Photographic Society in New York.

An almost entirely faded out photograph was shown by one member, which was given him to be copied, and he wanted to know how to accomplish it. One suggested to

lay it between two panes of glass and treat it like a transparent positive, and copy it by transmitted light. Another to restore the photograph by the aid of chloride of gold.

A weak gold bath, from two to three grains to twenty ounces of water, will be strong enough. Immerse the picture in this bath, but perform it in the dark room. After a few minutes, the picture will assume a darker colour, and appear more and more so after some time. When dark enough, it may be put in the fixing bath for about one-half minute, after which it must be carefully washed. The picture will keep now for a good while longer, and be found much easier to reproduce with better results.

Varnishing the Negative.—The subject of varnish was also brought up at the same meeting. It is a subject, too, of a great deal more importance than it is generally thought to be, and it ought to be considered just as much as the introduction of a proper background in the picture. There are a great many varnishes in the American market, and none of them are really bad, though some are superior to others.

The members of the Society present who devote their time to negative retouching, all expressed their opinion that there was no varnish in the market which possessed all the qualities required, and would very much like to see an improvement made in that direction.

Mr. Nagel, of Hoboken, said he had experimented for several years in preparing a varnish that would satisfy every requirement, and that at some future meeting he would lay before the Society samples of his production for investigation, and that he would give his recipe for publication. When he does so, I will gladly communicate it to you.

The receipts recommended by different members were as follows:—

1. Gum benzoin, one ounce; ten ounces alcohol.
2. Copal varnish, as ordinarily sold, mixed with two parts of benzine.

Another was recommended as the best:—

Dissolve melted amber in benzine to the thickness required.

The negative needs not much warming before coating. It gives a hard surface, and the heat to which our negatives are sometimes exposed during printing has no effect on this varnish.

Testimonial to Mr. Notman.—I clip the following from the *Montreal Daily Witness*, and as you know it relates to one of the most talented in our profession, you will be glad to give it place:—

"We are glad to learn that Mr. Wm. Notman has several times since Prince Arthur's return to England received large orders from his Royal Highness for his photographs, which are much admired in the old country. This week's mail brings an order from Her Majesty the Queen, who desires Colonel Elphinstone, in transmitting the order, to express her approval of these pictures."

This is a deserved tribute to a worthy photographer, and it should cheer us all to know that photography is appreciated and honoured by the patronage of royalty. Let us all honour our profession, and it will assuredly bring honour upon us.

Negative Retouching Varnish.—A few weeks ago, I gave you the formula for making Morgencier's Patent Varnish for giving a surface to negatives suitable for retouching. A little hint or two in using it may help along those who are trying it. If you intensify, use only pyrogallie acid, and do not intensify much, as the varnish tends to increase the density of the negative. A spotted appearance is the result of over-intensification. Cyanide is the best fixing agent. The plate must invariably be cool when varnished, though the drying may be hastened by heat if necessary, though spontaneous drying is best. An artist friend told me to-day that this is the best varnish of the kind known.—

Yours truly,
Philadelphia.

EDWARD L. WILSON,

GERMAN CORRESPONDENCE.

MORGENEIER'S INSTRUCTIONS IN RETOUCHING NEGATIVE AND POSITIVE PHOTOGRAPHS—SPLITTING OF THE FILM.

It is sometimes the case that excellent articles of highest practical value, published in any photographic or scientific journal, calls, at first, no attention at all; they are overlooked, whilst less important things are read, discussed, translated, &c. In this manner valuable hints are sometimes lost wholly, sometimes discovered by some cunning fellow, who knows to make somewhat from them.

This is, for instance, the case with the article of Mr. Hartmann, "On the Purpose and the Limits of Retouching," published in the July issue, p. 87, and August issue, p. 116, of the *Mittheilungen*, 1870; certainly one of the most excellent articles ever printed in this newspaper, though never republished in any other photographic journal. I guessed that that article would be overlooked wholly, and I got some days ago a very little American book, small shape, twelve pages long, entitled, "Morgeneier's Book of Instructions in Retouching Negative and Positive Photographs," and sold in America for one dollar and a-half. It is illustrated with two prints, carte-de-visite size, from the same negative, one touched up, and one not, in the negative. From the twelve pages of this one and a-half dollars book, two pages contain the preface and index, one page some recommending remarks over a new varnish (formula not given) invented by the author; of the remaining nine pages, four are filled with already known hints on retouching materials (among which is recommended again the new patent varnish of the author), drapery, landscape retouching (the last discussed in nine lines); the rest of the small book, five pages, and the chief part of it, gives instructions for retouching forehead, nose, eyes, cheeks, mouth, jaw, chin, and their chapters are nothing else than a merely verbal reproduction of the practical part of the above-mentioned Hartmann's article.

The only difference is an unimportant variation in the arrangement. In Hartmann's paper the chapters are arranged in the following manner: forehead, nose, mouth, eyes, cheeks, chin, mouth, neck. In Morgeneier's book is the arrangement: forehead, nose, eyes, cheeks, chin, mouth; but in each chapter Hartmann's paper is easily recognized, sentence for sentence; even his sentences follow with very little variation in the same order as in the original.

As I know that your valuable journal is much in circulation in the United States, I beg you to reproduce Hartmann's article in it; you can save in this manner for a good many of your American readers one and a-half dollars.

I have read, with great interest, the discussion in the London Photographic Society over cracking of the film, its causes and remedies. As I have been occupied with experiments over this point for a long time, allow me to give here some remarks on it.

It is ascertained by our photographers here that the failure easily occurs on plate glass, but very seldom on sheet glass. I have till now only observed it on plate glass. For determining whether insufficient washing will cause the failure, I took two pictures on sheet glass, fixed with cyanide, washed very imperfectly, and varnished. The two I brought in the dampest room at my laboratory, and sometimes I moistened them by putting on a piece of wet filter-paper. The plates are now nine months old, and in perfect order, without any trace of cracking. I am repeating now the experiment with plate glass.

In regard to the cracking of the film, I mention that the fine transparent lines are not fissures, as very often supposed; they are ridges more elevated than the other parts of the film, as I observed under the microscope.* The only difference between honeycomb cracking and splitting is, therefore, that the former is larger and easily visible in

* That the fine cracks described in a leader on another page as *rents* are really fissures is demonstrated by the fact that they are filled up when a fine powder or paste is rubbed over them.—Ed.

reflected light, the latter not; that the former disappears in alcohol vapour, the latter not. If the cracked film is rubbed in any way, even with a pure leather or the pure finger, without any colour, the film ridges are pressed down and disappear. The same is sometimes the case if the plate is gently heated, but, in the latter case, the cracks appear again by-and-bye.

If the cracked film is rubbed strongly, the film ridges are partially destroyed, and, afterwards, any colour is useful to fill out the fissures arising by rubbing. In regard to the proposed plan of Mr. England, to rub the cracked film with indian ink, I mention the curious fact I have published in the November issue, 1870, of my *Mittheilungen*, under the title "A Means for Avoiding Cracking of the Film," and reproduced in your News, Dec. 9, 1870, p. 582, that a plate touched partially on the varnished side with indian ink did not show any deterioration under the so inked parts, whilst the other parts cracked everywhere. I supposed that the gum contained in the indian ink had acted in this favourable manner on the plate; and, indeed, I succeeded perfectly in coating a plate with gum as indicated in the above-mentioned article. All parts covered with gum kept perfectly, whilst, in the other parts of the plate, the splitting of the film had gone on uninterruptedly. Even the gum must be employed in a very dilute solution, and applied with an almost dry brush, which, after dipping in the gum solution, is well pressed out.

All other water colours containing gum work in the same manner as indian ink; and it is only the presence of gum which acts so favourably in employing indian ink, as Mr. England advised recently.

I mention, lastly, that the presence of glycerine in colours acts very unfavourably, and causes splitting.

Berlin, March 25, 1871.

DR. H. VOGEL.

COFFEE AND OTHER DRY-PLATE PROCESSES, WITH PRACTICAL DETAILS

OF A NEW DEVELOPER GIVING EASE AND CERTAINTY.

BY A. DE CONSTANT.*

§ III.—THE COLLODION.

MANY distinguished chemists and operators have recognized and proved the fact that only a collodion of a powdery nature is applicable for the preparation of dry collodion plates. I have myself also published some experiments confirmatory of this view, and have indicated that Mawson's collodion (for iron development) appeared to fulfil all the conditions necessary to the successful working of dry plates; at the same time, I expressed a hope that manufacturers of collodion would supply a material specially suited for dry work, which could be always demanded under a certain name or number, so that photographers would always be certain of receiving a product of uniform and known quality.

Messrs. Mawson and Swan, acting upon this idea, have been good enough to forward me three samples of collodion which they believed especially suited for the purpose, and of those chosen, they contemplated preparing a supply for commercial purposes.

The comparative experiments made with these three samples of collodion again convinced me of the great importance of selecting an appropriate material for dry-plate work; all three samples were of excellent quality for ordinary purposes, but when employed in the preparation of dry plates, two of them exhibited a tendency to rise from the glass, and to become spotted with peculiar opaque rays, and only the third was sufficiently rapid in its action, and well suited for the special use for which it was required. This collodion, I may mention, can be obtained from Messrs. Mawson and Swan, under the designation of New No. 2, at a cost of ten shillings per pint. Although the iodizer supplied with the material answers its purpose very

* Continued from p. 139.

well in the ordinary way, I find it best to follow the advice of M. Gordon, and add thereto two grains of bromide of cadmium per ounce.

To those who would prepare their own collodion, I must recommend particular attention to the question of the pyroxyline; the advice of Dr. Monckhoven should be followed, viz., to choose a material which has been prepared at a high temperature, and which, known by its yellowish tint, is found to separate in hard rather than in fibrous particles, and is, moreover, full of dust. The Monckhoven collodion yields intense images which nitric acid fails to dissolve entirely.

If the photographer decide to renounce the preparation of collodion himself (which is wise), and it is desired to find out whether a material purchased is suitable for dry plates, it is sufficient to pour a small quantity thereof upon a glass surface, and, after setting, to rub the film with one's finger. If the collodion is rubbed into small particles, it will answer well for dry manipulation; whereas, if, on the contrary, it tears and separates from the plate in the form of ribbon, it is not fit for the purpose. In the first instance, a slight friction will reduce the film to powder, while in the second the finger will glide over the surface without injury. Finally, a suitable collodion, when sensitized and developed, will yield a hard and intense image, in which the shadows appear rapidly, and are extremely vigorous.

If I lay particular stress on this point, it is because I am fully persuaded that the greater number of failures experienced in dry-plate work result from the employment of a collodion unsuitable for the purpose. It is only, indeed, in this way that I can explain the cause of many difficulties which have come under my notice, when, for instance, pupils working with my process, who in my studio have executed most excellent *épreuves*, have on their return failed most unaccountably with their own collodion, which, nevertheless, gave with wet plates exceedingly good results. And if any other proof were wanting, it is to be found in my own experience, when by merely effecting a change in the collodion, I am able either to produce plates endowed with the most perfect preservative qualities, or, on the other hand, a film which readily loses its virtue at the end of a few days.

§ IV.—PREPARATION OF THE PLATES.

The plate, having been coated with collodion, and the film allowed to set, is immersed in an eight per cent. silver bath freely acidified with pure nitric acid. On its entry into the solution, it is moved to and fro at the bottom of the bath for a few moments, and then allowed to remain therein for four or five minutes. It is then removed, and, having been well drained, is placed in a bath of rain-water while a second plate is put into the sensitizing solution.

The first is then carefully washed in ordinary spring water (if the same can be obtained of good quality) under a tap covered up with a small linen bag to serve as filter; when the plate is freed from all appearance of greasiness, the washing operation may be considered to have gone far enough, and it is placed in a second bath containing rain-water, where it can remain until the time arrives to drain it and apply the preservative solution to its surface.

§ V.—THE PRESERVATIVE SOLUTION.

The designation of preservative is applied to numerous substances and mixtures which have been proposed from time to time for coating collodion films after having been sensitized and washed. At the same time it appears to me that the role attributed to such substances is by no means so important as generally imagined, for it is certain that the collodion film which we may desire to keep in a dry condition will only remain sensitive as long as it is in a porous and relaxed condition, and its molecules perform the function of tiny reservoirs, in which the iodide of silver may be stored up to be revived on development. This is, in fact, so true, that by means of a collodion endowed with a particularly favourable porous nature, dry plates may be

obtained by a simple washing of the film, and without the employment of any coating whatever; whereas, on the other hand, a horny collodion, in which the pores are so close that, on drying, an exceedingly hard and compact film is formed, the sensitive virtue of the plate is soon lost, whatever may be the nature of the preservative solution employed.

The best agent for the conservation of sensitiveness is, therefore, a suitable collodion; the subsequent coating of the plate should, nevertheless, be considered as an excellent aid in the matter, from the fact that saccharine, gummy, or viscid substances, which are generally employed in this capacity, act mechanically upon the porosity of the collodion, and thus there result more certainty and regularity in the preservation of the plates. It may be here asked, however, why, if the preservative only exerts a mechanical action upon the plate, there should have been so many modifications of the formulæ proposed. To this we would reply, that many of the various mixtures have been suggested for the main purpose of adding to the preservative solution some chemical agent possessed of a developing action which should have the effect of shortening the exposure or of softening the image; and it is with this design that new suggestions are made every day. Without in any way wishing at the present moment to deliver a course of chemistry, I propose to discuss a few of these questions which bear so much to the point.

Why is it that albumen processes always yield very clear results, but of a slow and hard nature, while those methods in which gum plays a part are to be distinguished, as a rule, by their rapidity, and the soft nature of their productions? Why are negatives prepared with coffee, tannin, and gum, although all of them developed in the same manner, with pyrogallie acid, of different colours, assuming a brown, red, green, or grey tint? I am told, in reply to these questions, it is probably the acid or alkaline re-action that produces the difference, and that a chemical analysis of the substances employed for coating would probably furnish an explanation. I admit the force of this answer, and believe that it would undoubtedly be a good thing to study the reaction and analysis of the solution to be employed as preservative, because that is the only right way to attain the end of one's purpose.

I will here describe a curious circumstance connected with this matter. Before I was well acquainted with the coffee process, it was my custom always to employ in the preparation of my preservative fluid just any coffee which I might have by me, until one day Dr. Liesegang informed me that Mocha was best adapted to the purpose. This led me on to institute a series of experiments with all the different kinds of coffees, and also to study their analysis, and the consequence was that I arrived at the conclusion that caffeine must be the active principle, from the fact that Mocha and Martinique, which contain the most, give the greatest rapidity, more delicacy and half-tone in the image, and, indeed, far superior results to St. Dominique, and certain Java coffees containing a quarter less of caffeine. I found, moreover, that a well-burnt coffee gave vigorous images of a dark brown character, while that roasted to a less degree yielded images of a greenish colour. It is to the caramel developed by roasting, which removes the chlorogenic acid, that the effect of the under-burnt coffee must be attributed.

When, some time ago, I first tried acetate of morphine recommended by M. Bartholomew, I found its action impeded the sensitiveness of the plate, while now Messrs. Gordon and England allude to it as a powerful accelerator. While endeavouring to reconcile two opinions so opposed to one another, I discovered that acetate of morphine is one of those pharmaceutical products which presents great variation in its preparation, being some times alkaline, and sometimes acid, in its character; and here, probably, is the explanation of the difficulty.

It was only after some consideration, therefore, that I

decided upon the combination of coffee and gum as a preservative, such as I employ at present; both of these agents have their special qualities, and profit by their association with one another to remedy mutual defects. And it is curious to find in what extraordinarily exact proportions it is necessary to use these substances in order to establish a favourable equilibrium. Thus, for example, by diminishing the proportion of gum, the harmonious softness, as likewise the rapidity of the plate, becomes impaired, while if more than half the quantity of gum is used, rising of the film and blisters are to be remarked.

The following is the mixture which I employ:—

No. 1. 150 cubic centimetres of distilled water, while in a boiling condition, are poured upon 15 grammes of Mocha coffee and 6 grammes of white sugar, both of the latter having been previously reduced to a fine powder.*

No. 2. 150 cubic centimetres of distilled water are used for dissolving 6 grammes of gum-arabic and 1·2 grammes of sugar-candy.*

The coffee extract is allowed to cool in a well-corked bottle, and both liquids are then filtered and mixed, forming together a clear brown liquid of a certain density, which will remain in good condition for several days. The quantity destined for each plate should be filtered and poured on like collodion; a second application of the liquid is made to the same plate, care being taken to prevent the formation of bubbles, and the solution should not then be further used. The coated plate is placed on end upon a sheet of filter paper to drain before being put into the drying closet which we shall presently describe.

Many operators apply the preservative by the aid of a horizontal bath, which is, perhaps, the easiest mode of proceeding; but in this way a larger quantity of solution is always necessary, and, moreover, the entire surface of the glass is soiled, so that the back thereof must afterwards be cleaned. For this reason the first method is recommended, which has, in my hands, always proved successful.

(To be continued.)

SKETCHES OF THE INTERNATIONAL EXHIBITION, 1871.

No. 2.—How I FETTERED MY PICTURES HOME AGAIN. BY THEOPHILUS THIDDLEMIDTCH.

THE Commissioners have no taste. I renounce them all. Not only have they rejected my pictures; not only have they informed me, with their usual polite sarcasm, that "the Committee of Selection did not recommend my pictures for exhibition," but, as if to add a purposeless injury to a senseless insult, the Committee has retained *one* of my pictures; the only one, I flatter myself, that any other photographer could have produced. This, sir, this is how I am to be represented; all the pictures on which I prided myself, all the pictures in which skill has been displayed, all the pictures which were compared in the *Times*, the *Telegraph*, the *Standard*, the *Daily News*, the *Court Circular*, the *Morning Post*, *Punch*, the *Record*, and—Oh! I beg pardon, I meant to put the *NEWS* first (if last, it is not least), as comparing favourably with the pictures of such men as Col. Stuart Wortley, have *not been recommended*. All the pictures in which the "one-eyed camera" has been supplemented in its mechanical action by every artistic faculty which I possess, have been returned, and the only one which has been recommended is a small portrait done by an assistant during my Christmas holidays, and sent to the Exhibition only to encourage its author, and not at all to represent my work.

* Stated in English terms about—

No. 1.—Distilled water...	5½ ounces
Mocha coffee...	¼ ounce
White sugar...	90 grains
No. 2.—Distilled water...	5½ ounces
Gum arabic...	90 grains
Sugar-candy...	20 "

It is hardly necessary for me to say that the impartiality shown in the rejection of my works of art has been accompanied with the most abject politeness; sarcasm was, no doubt, the basis and the root, but the fruit of the tree was sweet to the taste. The menials of lesser office had been ordered to *smile* and *bow* as my assistant went to bring home the pictures. They offered him string and brown paper, and even helped to tie the pictures up in a bundle! Then they ordered a cab to be brought, and saying unto him, "Good bye!" they seemed to suggest, "Please don't come here again; or, if you do, don't bring such good pictures."

So ends for me all interest in the Exhibition of 1871. I wonder if other photographers have been served the same! If so, there will be a nice little chorus join in to heave a gentle blessing on the Committee of Selection. By the way, I wonder if any of the *Committee* are photographers, and if they are going to exhibit their own works, and, if so, how many, or who is to *select them!*

Correspondence.

PICTURES RETURNED FROM THE INTERNATIONAL EXHIBITION.

SIR,—We have been recently informed that a great many exceedingly fine pictures have been returned from the Exhibition by the committee of selection. In some cases, we have heard the *best pictures sent* have been returned.

It is not easy to understand on what principle this has been done. It is not easy to suppose that all is not fair, but we think the public could best judge of this point themselves, if those photographers who have had some of their *best things* returned would give a list of them in the *News*. As there has been scarcely any photographic weather since last November, we may fairly suppose that the bulk of the photographs sent for selection were taken before the exhibition held in Conduit Street in November last, and many of the best may, therefore, be quite familiar to your readers and the public generally.

If several photographers would join the discussion which we invite, some opinion might be formed of the general style of the pictures turned out, and we should be then able to judge if the selection has been fairly impartial, such as would arise from simple limitation of space, or whether any one class of pictures has been eliminated in a way calculated to serve the private ends of individuals in authority. Without hinting at the slightest unfairness in the judges, we simply give a list of our pictures which have been rejected.

The following of our pictures—which, if we may judge their popularity, are not unknown to the public—have been returned: Returning Home—Sleep—The Foaming Shore—The Entomologists—Southborough Wood—The Edge of the Wood—Sunset on Culverden Down—The First Hour of Night—The Last Hour of Day—On the Common.

It is rather curious to notice that this list comprises our *best sunset and sea effects*, while of the others the two greatest favourites have been rejected.

We sincerely hope that other photographers will also publish their lists of rejected pictures.—Yours truly,

ROBINSON AND CHERRILL.

SIR,—As curious rumours are circulating as to the class of pictures rejected at the International Exhibition, I send for publication in the *News* a list of the pictures sent by me, which have been rejected, the rejections consisting, as you see, all of large figure studies, which, in the Photographic Exhibition, were fortunate enough to win high praise from critics.

1. A portrait study.—2. Lady in white fur jacket.—3. Lady in white silk (full length).—4. Italian girl.—5. A gentleman in Spanish costume.—6. A lady in white.

All those having been specially commended by the press being thus rejected, I think I may fairly ask, "What does it mean?"—I am, yours truly,

VALENTINE BLANCHARD.

48, Piccadilly.

SIR,—If the reports which are freely repeated in photographic circles be true, photography will present a very sorry show at the International Exhibition. I hear in all directions

that the best pictures are rejected, and the worst retained, and, what is worse, motives are suggested which I am afraid you would not print, even were I to repeat them. My object in asking you to publish this letter is to prevent photographers, if these rumours be true, submitting to a degradation. Exhibitors generally well know if the story be true, and if so, would it not be wise for them to combine and withdraw their pictures from the Exhibition altogether? It would be better that photography should not be represented at all than that it should be misrepresented.

It is reported that large instantaneous pictures of sea and cloud, and large figure studies, are generally rejected, and, amongst other things, the exquisite little genre picture which won universal admiration, "Stolen Moments," by Mr. Hubbard, who only sent besides two little things, 5 by 4, and one 12 by 10. The absence of that picture alone would make the Exhibition incomplete.—Yours,
NEMO.

[Surely the rumours to which our correspondent refers must be erroneous. The idea that the Committee should of intention keep the worst and reject the best is incredible.—Ed.]

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

DEAR SIR,—You have, I see, taken exception to the weak point in my illustration, which was an extreme one, I admit, assumed to give force to my argument. But I still think the spirit of what I have said holds good. Even if A, B, and C send pictures of equal merit, though, perhaps, of different styles of art, is it fair to hang only two of C's examples, and twenty-five of A's, simply because C is the most moderate, thereby giving (frames being equal) A twelve times the space allowed to C?—I remain, with apologies for thus troubling you, dear sir, yours faithfully,
A CONSTANT SUBSCRIBER.

[The merit and interest being equal, it would not be fair to devote twelve times as much space to one contributor as that devoted to another, simply because the latter had been modest in his demands, nor do we think that the space has been apportioned in such a ratio. We doubt very much if any one has twenty-five frames hung. But supposing A send twenty pictures all of great excellence, and including varied styles, such as landscapes, portraits, &c., and B send ten pictures, all of one kind, and some of them, in the opinions of the committee, of moderate merit, we think they would be justified in hanging ten of the contributions of A, and only five of those of B. We simply suppose one possible example to show how many circumstances may exist to influence the decision of a committee, and how difficult it is to judge a committee placed under such circumstances until its reasons, as well as its decisions, are before the public.—Ed.]

TESTING SILVER SOLUTIONS.

DEAR SIR,—On reading over the "American Correspondence" in the News of last week, whilst thanking our transatlantic friends for many valuable hints and improvements, I consider that it would be acting unfairly to a large number of photographers, and also most unjustly towards one individual, did I not say a few words about F. W. Hart's volumetric apparatus. It is cheap, simple, and most effectual. It only costs 10s. 6d., to begin with, in a neat mahogany box. I have used mine for six years, and it is as good as ever, and, no matter what is in the bath, you can easily, in a very few minutes, test its strength to a grain. When I say no matter what is in your bath, I mean, of course, any such ingredients as are usually put in in common use. Whether it would be useful in case of lead or mercury I cannot say; but I am certain Mr. Hart can at once supply the information. It might be useful even to know this, for by accident something of the kind might get in. Some years ago I had engaged an assistant from London; in fact, that assistant brought with him, at my desire, from Mr. Hart, the apparatus. It so happened that I was one day from home, and the assistant commenced to tone, as he supposed, with the toning bath; but it chanced to be the sensitizing bath, and, finding that it did not tone, he added gold, and it was some time before he discovered the mistake. Of course, a considerable quantity of the silver was precipitated, but I did not know how much; but the volumetric apparatus soon put all right, and after strengthening the bath—after filtering, of course—I found that it was as good as over. I mention the above to show how simply an accident may occur. The baths were not near each other, nor was it ignorance, but gross carelessness.

I hesitate not to say that no photographer should be without one. Of course an experienced printer can at once tell by the appearance of his prints whether or not his bath is strong enough or too strong, but he may sometimes be deceived. I remember about two years ago I was very busy, and did not attend to my printing bath. I usually work it about 40 grains, and I supposed it to be then about 35 grains. I was getting splendid prints—if anything, too brilliant; but all at once they began to bronzo very much in the shadows. I tested, and found it only 26 grains. I strengthened to 40 grains, and all was right again. I have since used the volumetric apparatus more than ever, and with my negative bath I have had the same comfort in using it.

I have, however, said far more than I intended, but the subject is an important one, and I trust to your well known desire to let everyone say their say.—I am, yours truly,
Newry, Ireland, March 27th, 1871. D. WELCH.

P.S.—I forgot to say that with the apparatus for testing nitrate of silver solutions, at above price, is also included apparatus for testing the quantity of silver in chloride of silver residues, and I can also say that it is most efficient. D. W.

A SIMPLE PRINTING FRAME FOR OPAL GLASS.

SIR.—A simple plan for printing opalotypes without a special frame is as follows:—

Take a strip of paper five-eighths of an inch wide and the length of your plate, and gum a quarter of an inch on the plain side of the negative, and a quarter of an inch on the plain side of the opal glass; it can be then printed in an ordinary frame, and examined without any fear of putting out of place.—Yours truly,
A. HARRISON.

Proceedings of Societies.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL meeting of this Society was held March 2, at 12, York Place, Portman Square, ARTHUR FARRE, esq., M.D., in the chair.

The minutes of the last meeting having been read and confirmed, the following candidates were elected members:—Miss Bayly-Williams, S. Samuinn, esq., and J. H. Fetherston-II., esq.

The SECRETARY then laid before the meeting the pictures of the current year, and Mr. GLAISHER read the annual report, of which the following is an abstract:—

It has been my agreeable task, every year since the foundation of this Society, to congratulate the council, not only on the excellence, but also on the improvement in the negatives contributed, compared with those of the previous year; but this time, I am sorry to say, the pictures do not quite reach the point of excellence which was attained last year; the number of pictures are about the same, but, in the matter of excellence, we have, if anything, retrograded. Some of our members who have regularly sent in a large number of continental views of the highest excellence have been prevented this year by the war from sending any, and the tremendous events which have happened during the summer and autumn of the past year, riveting the attention of every intelligent observer, do more than account for this slight check in the progress of the Society. Mr. F. G. Lloyd, who exhibits this year for the first time, and Mr. Schwabe, merit high commendation. Capt. Bankart and Major Gresley, although always good, are below their usually high standard of excellence; in Mr. Murray's dry plates we perceive an improvement which should not pass unnoticed. Mr. T. W. Richardson has sent a number of fine plates, but, owing to some defect in the varnish, they have 'spidered,' so as to become useless. From Capt. Allen we have a large series of well-chosen pictures, which, had they been a little more exposed, would have ranked in the highest class. Dr. Sinclair Holden, too, has sent some cleverly-arranged pictures, which, but for injudicious lighting, would also have ranked high.

The number of pictures in class 1 is 63, in class 2 is 84, in class 3 is 197, in class 4 is 257, in class 5 is 203, class 6 comprises the remainder.

Class 1 contains 63 pictures as follows:—

Capt. Bankart, 9; Capt. H. White, 9; F. G. Lloyd, esq., 6; G. Bevington, esq., 3; Rev. T. Hervey, 3; F. P. Barlow, esq., 3; W. Baily, esq., 3; F. Bensley, esq., 2; R. Murray, esq., 2; F. S. Schwabe, esq., 2; B. Green, esq., 2; T. Higgin, esq., 2; Capt. F. M. Allen, 2; W. J. A. Grant, esq., 2; Capt. J. C. A. Lewis, 2; R. C. de la Coudamine, esq., 1; W. L. Bauks, esq., F.S.A., 1; F.

K. Barelay, esq., 1; W. S. Hobson, esq., 1; Rev. H. Holden, D.D. 1; H. Day, esq., M.D., 1; A. R. Hunt, esq., 1; J. W. H. Watling, esq., 1; T. Samuels, esq., 1.

Class 2 contains 84 pictures, as follows:—
 Capt. Bankart, 17; Capt. H. White, 7; F. Beasley, esq., 4; W. S. Hobson, esq., 4; F. G. Lloyd, esq., 4; J. McAndrew, esq., 4; Major Gresley, 3; G. Bevington, esq., 3; T. Brownrigg, esq., 3; J. W. Richardson, esq., 3; Rev. H. Holden, 2; Capt. J. C. A. Lewis, 2; B. Greene, esq., 2; T. Higgin, esq., 2; W. M. Chamby, esq., 2; Col. Sir H. Halford, bart., 2; W. J. A. Grant, esq., 2; W. L. Banks, esq., 1; R. Murray, esq., 1; Rev. J. Freke, 1; H. Day, esq., M.D., 1; W. Baily, esq., 1; F. S. Schwabe, esq., 1; R. C. Walker, esq., 1; A. R. Hunt, esq., 1; Capt. F. M. Allen, 1; J. Caldwell, esq., 1; J. W. H. Watling, esq., 1; S. Samuels, esq., 1.

Class 3 contains 197 pictures, as follows:—
 Capt. H. White, 17; A. R. Hunt, esq., 12; Capt. Bankart, 10; H. Day, esq., M.D., 9; G. Hutchinson, esq., 8; C. Stephens, esq., 7; F. Beasley, esq., 8; W. M. Chamby, esq., 7; F. K. Barclay, esq., 6; Capt. F. M. Allen, 6; J. G. Lloyd, esq., 6; W. S. Hobson, esq., 5; R. Browne, esq., 5; Col. Sir H. Halford, bart., 5; W. J. A. Grant, esq., 5; Lt.-Col. Biggs, 4; Rev. S. Hervey, 4; T. Higgin, esq., 4; J. Caldwell, esq., 4; R. Murray, esq., 3; T. Pryce, esq., 3; J. W. Richardson, esq., 3; Capt. J. C. A. Lewis, 3; J. S. Holden, esq., 3; W. M. Wemyss, esq., 3; Miss Cumby, 3; Major Gresley, 2; R. C. de la Condamine, esq., 2; W. L. Banks, esq., F.S.A., 2; W. H. Pryce, esq., 2; J. S. K. Moss, esq., 2; T. Brownrigg, esq., 2; Rev. H. Holden, D.D., 2; W. S. T. Sinclair, esq., 2; J. H. Craigie, esq., 2; W. Baily, esq., 2; R. C. Walker, esq., 2; T. W. Parker, esq., 2; J. S. Livesey, esq., 2; G. Bevington, esq., 1; Sir J. J. Coghlin, bart., 1; F. E. Curry, esq., 1; L. Ashburner, esq., 1; F. P. Barlow, esq., 1; T. Bags, esq., 1; Capt. Foster, 1; G. Dundas, esq., 1; B. Greene, esq., 1; J. W. H. Watling, esq., 1; J. McAndrew, esq., 1; R. Meade, esq., 1; T. Samuels, esq., 1.

Class 4 contains 237 pictures, as follows:—
 Capt. H. White, 27; A. R. Hunt, esq., 17; R. C. de la Condamine, esq., 12; W. H. Pryce, esq., 11; C. Stephens, esq., 9; W. L. Banks, esq., 8; H. Day, esq., M.D., 8; W. J. A. Grant, esq., 8; R. Murray, esq., 7; J. W. Richardson, esq., 7; Capt. W. Foster, 7; J. Caldwell, esq., 7; F. G. Lloyd, esq., 7; J. McAndrew, esq., 6; F. Beasley, jun., esq., 5; T. Pryce, esq., 5; Capt. F. M. Allen, 5; G. Bevington, esq., 4; F. E. Curry, esq., 4; F. K. Barclay, esq., 4; A. Gray, esq., 4; L. Ashburner, esq., 4; F. P. Barlow, esq., 4; F. J. McLaren, esq., 4; A. Booty, esq., 3; J. S. K. Moss, esq., 3; W. G. Hunter, esq., 3; Rev. H. Holden, D.D., 3; W. Adcock, esq., 3; R. Brown, esq., 3; Miss Cumby, 3; T. Higgin, esq., 3; T. W. Parker, esq., 3; J. W. H. Watling, esq., 3; Rev. T. P. Ravenshaw, 2; Col. Biggs, 2; Capt. Bankart, 2; W. S. Hobson, esq., 2; T. R. Lane, esq., 2; J. S. Holden, esq., 2; B. Greene, esq., 2; Col. Sir H. Halford, bart., 2; G. Hutchinson, esq., 2; J. S. Livesey, esq., 2; Sir J. J. Coghlin, bart., 1; T. Brownrigg, esq., 1; Rev. T. Hervey, 1; J. Guyton, esq., 1; Rev. J. Freke, 1; J. H. Craigie, esq., 1; J. H. Ritchie, esq., 1; W. M. Wemyss, esq., 1; Capt. Arbuckle, 1; R. C. Walker, esq., 1; G. Dundas, esq., 1.

Classes 5 and 6 contain the rest of the pictures.
 The following prizes were awarded by the council:—
 F. G. Lloyd, esq., for Nos. 1, 20, and 28—a silver goblet.
 F. S. Schwabe, esq., for Nos. 18 and 19—a silver goblet.
 Capt. Bankart, for Nos. 175 and 179—a silver goblet.
 W. J. A. Grant, esq., for Nos. 11 and 24—an oil painting in gilt frame, by C. Frisch, esq.
 Rev. T. Hervey, for Nos. 86, 87, and 89—an oil painting, in gilt frame, by C. Frisch, esq.
 T. Higgin, esq., for Nos. 20 and 21—a large album, elegantly bound in morocco.
 W. Baily, esq., for Nos. 21 and 22—an oil painting, in gilt frame, by C. Frisch, esq.
 J. H. Watling, esq., for No. 4—an album, elegantly bound in morocco.
 Capt. H. White, for Nos. 18 and 51—an album, elegantly bound in morocco.
 F. P. Barlow, jun., esq., for Nos. 131 and 138—an album, elegantly bound in morocco.
 G. Bevington, esq., for No. 7a—an album, elegantly bound in morocco.
 W. H. Chamby, esq., for Nos. 2 and 11—an album, elegantly bound in morocco.
 Capt. Lewis, for Nos. 32 and 31—an album, elegantly bound in morocco.
 B. Greene, esq., for Nos. 22 and 28—an album, elegantly bound in morocco.

DRY-PLATE PRIZES.

R. Murray, esq., for Nos. 38 and 41—an oil painting, in gilt frame, by C. Frisch, esq.
 F. Beasley, jun., esq., for Nos. 131 and 132, a large album, elegantly bound in morocco.

Certificates of honourable mention were awarded to the following members:—
 R. C. de la Condamine, esq.; W. L. Banks, esq.; F. K. Barclay, esq.; W. S. Hobson, esq.; Rev. H. Holden; H. Day, esq., M.D.; R. Hunt, esq.; Capt. F. M. Allen; S. Samuels, esq.

A vote of thanks was passed by the meeting to Mr. Glaisher for the time and attention which he had bestowed upon the examination and arrangement of the pictures, and for his very able report.
 A. J. MELNITSIN, Hon. Sec.

Talk in the Studio.

WHERE TO GO WITH THE CAMERA.—A correspondent suggests that at this season of the year, when amateurs are beginning to anticipate pleasant summer tours and photographic reminiscences of them, photographers might aid each other much by forwarding for publication in our pages suggestions and information regarding places they have visited, and which provide inducements for men and cameras. We shall have pleasure in receiving and publishing the hints of any of our correspondents.

THE "PHOTOGRAPHIC TIMES."—Another new photographic journal has just been issued in America. Like the *Photographic Bulletin*, it is avowedly intended as an advertising medium, being issued by the Scovill Manufacturing Company for gratuitous circulation. It is not solely devoted to advertisements, however, but contains much interesting readable matter, which will make it welcome to all photographers. It is also well printed, and in all ways creditably got up. The Scovill Manufacturing Company is not solely devoted to photography, but is the great American head-quarters for most kinds of fancy metallic goods, buttons, plated wares, &c.; but we understand that the photographic department alone is larger than any other single photographic warehouse in the world. When this is remembered, it can be better understood how such an establishment can send out a gratuitous journal for advertising purposes.

COMPENSATION TO A PHOTOGRAPHER.—At the recent Assizes held at Hereford, Mr. Beechervaise, a photographer, residing at Pembroke Dock, South Wales, brought an action against the Great Western Railway Company for injuries received in a collision. Mr. Kenealy, Q.C., and Mr. Cleave were for the plaintiff; Mr. Huddleston, Q.C., Mr. Hill, Q.C., and Mr. J. O. Griffiths were for the defendants. The plaintiff was a third-class passenger by the defendants' line from Malvern to Milford on the 25th of November, 1869. When the train had just left the Hereford station, and had got about 150 yards, it ran into a carriage which had been left on the line. The negligence of the signalman was the cause of the accident. The plaintiff was thrown forward against a passenger sitting opposite to him. When he got to Newport he got the station master to send him to an hotel, and to procure a surgeon for him. On the 27th of November he continued his journey to Pembroke. His eyes had been affected as well as his spine, and he had not been able to earn anything as a photographer since. He had previously earned about £3 a week, and he had been put to expense in seeing doctors. He was severely cross-examined as to his antecedents. The jury found a verdict for the plaintiff—damages, £400.

PHOTOGRAPHY AIDING ART.—We understand that the belt of designs in mosaic by great modern artists which runs round the Albert Hall was indebted to photography for a part of its production. The belt of mosaic work is 6ft. 6in. wide, and more than 800ft. long. The drawings of the artists were first enlarged by photography; the mosaic work was put together at the Kensington Museum by the lady students of the Arts Schools; and the slabs thus produced were fixed in Portland cement to the wall.

PHOTOGRAPHING THE INVISIBLE.—In an article on photographic miracles, *Licht* mentions some curious cases in which objects invisible to the human eye are practically visible to the photographic lens, and make a visible impression on the sensitive tablet. "Letters which have been written with the

colourless solution of the sulphate of quinine on white paper are to the human eye perfectly invisible. When the photographic camera is directed upon a sheet of paper covered with such writing, the negative will show the characters transparent on a dark ground, and a print would show them black on a white ground. We remember a case where, in copying an old map, all the negatives were covered with transparent spots, the origin of which could not be traced to any fault in the photographic process. A story is told of a lady who had her portrait taken; the print showed the face covered with spots, the origin of which could not be traced. A few days later the lady took the small-pox; the invisible spots had impressed themselves upon the plate. Of all these cases, we can only call the first one as wonderful, because we have to be satisfied with the fact, without being able to state the reason why the salt of quinine absorbs the chemical rays. In the second case the spots could be observed by inspecting the map very closely, and this might possibly have been the case also with the face of the lady, supposing that the story is true."

"EUROPEAN STYLE."—A correspondent sends us a cutting from a Boston (U.S.) paper, in which a photographer announces his scale of prices. Although the phraseology is quaint, it is gratifying to note that the prices, described as "medium between extremes," are at a remunerative rate, card portraits in the "European style" being charged about two guineas a dozen. The advertisement runs thus:—"Photographs—Best American style cards, \$3 25 per dozen; European style cards from retouched negatives, \$10 per dozen; cabinet cards, \$3 for three; four card Ferrotypes (large size), \$1. I make the best pictures that are made in Boston, because I make all sittings myself. No boy's work. The prices are medium between extremes."

THE CASE OF MR. EVANS.—Mrs. Evans writes as follows in the *Standard*:—"Sir,—The kindness with which you, in last October, opened your columns to me for an appeal for consideration of the case of Henry Evans, emboldens me again to trouble you. That appeal, supported by facts, attested by the signatures of 300 gentlemen connected with art, failed of its effect at the Home Office. Since that date, the sad effects of imprisonment and anxiety on the health, bodily and mental, of the prisoner, induced me, though indeed reluctantly, to make a fresh appeal, this time *ad misericordiam*, and I ask you, sir, to place before Mr. Evans's numerous friends and the public this simple record of the tender mercies of the Home Office. I visited Mr. Evans on March 1, 2, 3, and 18, and found him in a state of fearful depression, unable to converse, and, indeed, scarcely capable of sustained recognition; he had altogether lost the sight of one of his eyes, and was almost unable to walk. Mr. Evans's former medical attendant also visited him, and his opinion is given as follows:—(Copy No. 1.) '40, Endell Street, W.C. March 3. I hereby certify that I have this day visited Henry Evans, a prisoner in Coldbath Square, and that he is suffering from extreme debility, calculated to bring on softening of the brain, &c. He has also lost the use of one of his eyes, and, in other respects, is suffering from the effects of his imprisonment. Having professionally attended him for several years past, I am of opinion that a further detention will have the most disastrous consequences to his general health, and therefore strongly recommend his case to consideration.—WILLIAM FAULKNER, M.R.C.S., Registrar, St. Giles, &c.' On two different occasions two old friends also visited Mr. Evans, and their own words best convey their impressions:—(Copy No. 2.) 'On the 2nd of March 1871, I visited Henry Evans in the infirmary of Coldbath-Fields Prison, and, having known him seventeen years, I was grieved to find the great change the year's incarceration has made in him. He was unable to sustain any connected conversation, almost an imbecile, hardly able to walk, so that I could with difficulty recognise him.—RICHARD REEVES. March 20.' (Copy No. 3.) 'I saw Henry Evans at Coldbath Prison on the 18th inst., and was shocked to find a man whom I had known for twenty-three years as an intellectual being so prostrated mentally and bodily. In answer to questions put to him, he replied either in monosyllables, or more frequently gave such strange answers, that I cannot think he is in his right mind.—BRUCE MORRINE. March 20, 1871.' In deep distress, I forwarded a petition to the Home Office, stating the present condition of Mr. Evans, as shown by the medical certificate. The answer came in the stereotyped form:—'Mr. Secretary Bruce having carefully considered your application, I am to express to you his regret that there is not sufficient ground on which to grant your petition.' Thus, it seems

but too probable that Mr. Evans is only to exchange Coldbath Fields for a lunatic asylum or the grave.—I am, sir, your obedient servant, MATILDA EVANS, 14, Castle Street, and 1A, Endell Street, Long Acre, W.C., March 22."

To Correspondents.

TO AGENTS AND ADVERTISERS.—Next Friday being Good Friday, the *PHOTOGRAPHIC NEWS* will be published on Thursday, April 6th. Advertisers should send in their Announcements not later than Wednesday, the 5th.

SOUTH DEVON.—The addition of gum to the coffee solution increases the sensitiveness of the plate. 2. It is probable that it will somewhat decrease its keeping qualities; but of that we cannot speak with practical certainty. 3. So much depends on individual necessities and proclivities, it is impossible to advise you which to adopt. If we contemplated devoting ourselves to either, we should try both first.

J. MALEB.—You must copy a glass positive in the same way in which you would copy any other picture, but with certain precautions. The positive must be placed so as to avoid false reflections from its polished surface. In fact, it should be treated, in copying, much in the same manner as a Daguerreotype. Read Mr. Hughes's article on copying Daguerreotypes in our last YEAR-BOOK. Or if the positive be a fully exposed one, obtain a transparency on wet collodion in the camera from it, and from the transparency produce the required negative. 2. The object of a cone is to lengthen the camera, and enable it to be extended sufficiently for copying without reducing the size of the copy. 2. American cloth may be used for the body of a bellows camera, but it is not so good as leather, being more liable to crack in the corners. 4. Collodio-albumen plates are developed first with a solution of pyrogallie acid without any addition, and when the image is out, with ordinary pyro solution containing acetic or citric acid and a little silver solution.

A. B.—The building which intercepts your light should decidedly be white-washed, it will then give you reflected light.

CALEBERG.—Details of M. de Constant's mode of developing will be found in the articles of that gentleman, which we are now publishing.

EX UNO DISCE OMNES.—A transfer albuminized paper for permitting the albuminized film to be transferred after printing, used to be prepared in Berlin; but we do not know whether any one now keeps it in this country. Try Mr. Hughes's warehouse, or that of Mr. Solomon. The latter gentleman keeps collodio-chloride transfer-paper for a similar purpose.

J. R. TANNER (Australia).—It was a large continental portrait lens, but we do not know the maker nor the cost. 2. We do not usually undertake such duties, but we will, in your case, make a selection of prints for you when you remit, as your remote isolation affords so little opportunity of knowing what progress is made in the art. Your specimens have many good qualities, being soft, delicate, and harmonious; but they lack force a little, the light being too uniform and diffused. A little more intense light from one side, and a little less front light, will give more relief and brilliancy to the pictures.

A. BELL.—We think that the modification giving you north light in the roof is decidedly an improvement. 2. The south light through tracing-linen will often be useful. 3. In dull weather you may use the direct south light. 4. For children, both lights may be useful.

JOHN STONE.—It is difficult to state what is the best box for drying plates. Most dry-plate workers improvise something for themselves. We have seen an old chest made light-tight, and heated by means of one or two hot bricks, made available. We use, ourselves, a deal box with a funnel-shaped tube running up the centre, at the bottom of which, outside the chest, we can either place a gas jet or a spirit-lamp. Two or three conditions should always be observed in making a drying-box: it should be light-tight, but not air-tight, as damp air is required to escape. It is well, therefore, to have a double top, each portion being perforated, but the perforations not occurring in the same place. Glass rods, or small glass tumblers, are better to rest the plate on than blotting-paper.

JAMES SUGG.—The numbers you require are procurable, and can be sent at once on receipt of the stamps.

ORGANIC ADDITIONS TO THE IRON DEVELOPER.

From the general tendency of the bulk of the evidence which reaches us, we have noticed a prevalent recurrence amongst photographers to the use of the simple iron developer, and the abandonment of the various forms of the gelatinic addition which were so extensively used for a short time after they were first proposed by Mr. Carey Lea. In the course of some recent experiments, we took occasion to re-test our former conclusions on the subject, and in each instance found former experience verified. Where great intensity was desirable, as in copying subjects in black and white, we found that the addition of a trace of glycocine to the iron developer was most valuable, but it unquestionably prolonged the exposure. Molasses retarded most, and sugar or honey least. We do not intend here to enter upon a detailed statements of these experiments, but to refer to some recently made by Dr. Stolze, and described in *Licht*, of which he is the editor; and in mentioning the details and results of his experiments, we may state that in almost every instance they are confirmed by our own experiences. Believing that many of the opinions published on the subject were not the result of systematic and comparative experiment, he resolved to make a series of experiments with six developers of different composition. In all the experiments an ordinary iron developer served as the normal solution, and a certain quantity of different kinds of organic matter was added to each.

The proportion of the organic matter was equal to one-sixth part of the quantity of sulphate of iron.

The developers were—

1. The ordinary iron developer.
2. The ordinary iron developer with loaf-sugar added.
3. The ordinary iron developer with milk-sugar added.
4. The ordinary iron developer with caramel added.
5. The ordinary iron developer with gelatine added.
6. The ordinary iron developer with glycocine added.

In all the experiments, in order to make the different tests under exactly similar circumstances, a large plate was exposed in the camera, and cut with a diamond in six parts; each part was developed with one of the developers above described.

The result was, that the solution with loaf-sugar permitted the shortest exposure, the ordinary developer came next, then followed the developer with gelatine, which gave a very vigorous picture. The glycocine developer gave only traces of a picture, and those with caramel and milk-sugar made hardly any impression on the plate. The latter would only with a very long exposure produce a similar result to developers Nos. 1, 2, and 5.

The experiments were subsequently repeated. The pattern of a carpet was photographed on a large piece of

plate-glass. The plate was divided in six zones. Each zone was developed with a separate developer. The developers had not been freshly prepared, but were two weeks old. The temperature of all of them was exactly alike. The result was surprising, for it showed that the organic matter in the developer becomes changed in a short time, and exceptionally in such a manner that the freshly prepared developers are more effective than the old ones.

The result was the following:—

- No. 1. Develops most rapidly, but has a tendency to fog.
- No. 2. Develops a little more slowly, but very brilliant; the shadows are perfectly clear.
- No. 3. Develops still stronger; brilliant, and free from veil and fog.
- No. 4. A little slower than No. 3; weak, and decided fog.
- No. 5. Very slow, weak, and very foggy.
6. Still slower, and completely fogged.

While with the freshly prepared developer No. 2 worked most rapidly, and the others followed in the following order—1, 5, 6, 4, 3—it will be noticed that the older developers, so far as rapidity of work was concerned, stood in the following numerical order: 1, 2, 3, 4, 5, 6; but No. 2 was decidedly preferable to No. 1, on account of the great brilliancy and the clearness of the shadows. No. 5, which, when freshly prepared, worked clear, brilliant, and vigorous, became, after having been kept for two weeks, utterly useless. No. 3, which, when fresh, gave the worst results, follows, when old, directly after 1 and 2.

The conclusion of Dr. Stolze is similar to that we have often expressed, that the addition of loaf-sugar is an advantage to the developer, but that, except for intensifying purposes, most of the organic additions which have been proposed are undesirable.

AMERICAN CORRESPONDENCE.

HOW TO VIEW STEREOGRAPHS WITHOUT A STEREOSCOPE—A PATENT FOR THE USE OF HYPOSULPHITE OF SODA IN PHOTOGRAPHY.

How to View Stereographs without a Stereoscope.—To say the least, it is very convenient to be able to secure the solid or stereoscopic relief without the aid of the "scope." Those who are extensively engaged in the manufacture of stereographs, and others, will appreciate this. Pictures often get separated, and are mismounted in spite of care taken to prevent it; whereas, if the mounter possessed the above-mentioned faculty, no mismounting would occur. A "scope" is not always at hand; and, if it were, time would be lost in adjusting it, &c.

I will endeavour, in as few words as possible, to explain

bow any one may acquire the habit. It will be of great service to all who have anything to do with selling, mounting, or enjoying stereoscopic pictures. There are several ways of accomplishing the thing, but the simplest and easiest is the following, which has been communicated to me by Mr. C. S. Zimmerman, an accomplished landscape photographer in St. Paul, Minnesota:—

"Hold a stereograph before you, as near as possible level, about the height of the eye, and (say) fifteen or twenty inches distant; now glance immediately over the centre of the card at an object beyond—on the wall, for instance. You will see not only the object on the wall, but you will perceive that the 'right' and 'left' of the stereo have slid together, and partially overlap; then slowly lower the eyes to the centre of the card, and the two pictures will entirely overlap; you see, instead of two pictures, three, the centre one of which presents the stereoscopic relief. By placing a dividing card against, and at right angles to, the stereo, only one picture will be seen, and that having good relief. After a little practice, you will be able to secure the effect as readily as with a 'scope,' and with much less fatigue to the eyes."

When once acquired, this little accomplishment will be found of immense value.

Patent for the Use of Hyposulphite of Soda in Photography.—It has often been jocularly remarked, in this country of ridiculous patent claims in photography, that the next demand made upon photographers would be for royalty for the use of "hypo." Sure enough it comes sooner than we expected. A couple of enterprising Rip Van Winkles, down in "My Maryland," have obtained a patent for the use of equal parts of hypo and bicarb. soda as a "detergent." They see a "big thing" for them among the photographers, and have made the attack. It is my notion, however, that they will be repulsed.—Yours truly,
Philadelphia. EDWARD L. WILSON.

PRINTING ON IMPERMEABLE PAPER.

BY WILLIAM BLAIR.

THE recent remarks by Mr. Stokes and others on the desirability of obtaining a paper for photographic purposes that will be impervious to moisture may, perhaps, be a sufficient apology for me to notice one or two things that have come under my own observation in attempting to use this sort of paper for silver printing. Being desirous to turn india-rubber paper to some account for printing either negatives or positives on its surface by means of chlorized albumen, and afterwards transferring these to another support, I met with failure and disappointment. I coated the rubber surface with salted albumen, and some of it got a double coating; then sensitized by floating on a 40-grain bath in the usual way, and exposed in the pressure-frame, both under negatives and positives. My first papers darkened in patches, leaving whitish blanks of considerable size, and many small blanks. I blamed the cold weather, and too short flotation, &c., and tried again, heating the bath, and floating for half an hour and more; but still, on exposure, the surface darkened irregularly, and with a marked degree of granularity, although the large blank patches seen in the first papers had now disappeared.

I tried common paper prepared at the same time with the same albumen, and found no such defects. I was thus induced to think that the india-rubber, or traces of its solvent, still in the paper, must have induced an electric repelling action in the silver bath, preventing the regular formation of the chloride of silver in the albumen. At the same time it appeared possible that the impermeability of the paper may have prevented the bath from displacing the air in the albumen, and so opposed the admission of the silver in sufficient quantity when the usual mode of flotation was adopted; and that, in order to get such paper sensitized

properly, it should either be immersed in the bath face upwards, or a brush used to spread the sensitizing fluid over its surface. I tried the latter method, and found that I could succeed in this way much better than by floating.

Having now got a tolerable expression on this paper, I tried to lift it from the paper by coating it with gelatine, and, when dry, using benzole to effect the separation; but I did not succeed satisfactorily. In the first place, there seemed to be a difficulty in fixing the print in the hypo; some prints that I thought sufficiently fixed at the time, and, indeed, had to be withdrawn in consequence of being over-reduced, afterwards darkened in patches on continued exposure to light; and I thus found that the pictorial impression had not confined itself to the albumen, but had affected the india-rubber, and entered it to an extent that the hypo had failed to reach. I had, moreover, a difficulty in separating the albumen print from the paper, and in so far as I did succeed, it was a mere phantom impression that came away with the gelatine, the body of the impression remaining on the paper or on the rubber.

I went through a similar process with waxed paper. I found no difficulty in sensitizing the albuminized surface of waxed paper by flotation, showing that the wax is more absorbent than india-rubber, and has not the same tendency to disturb the chemical affinity of the sensitive salts. Neither did there seem to be any difficulty in fixing the print. But again, on attempting to remove the print from the waxed paper by means of gelatine, I found that only a mere phantom print came away with the gelatine, and that the impression left on or in the waxed paper was by far the denser of the two.

These simple trials seem to support the remarks that have been made, that for ordinary silver printing it is very difficult to get a substance that will entirely exclude the admission into it of the silver salts; and if such a substance be got, the albumen would be required to be laid on in considerable thickness, in order to get a forcible picture. Probably waxed glass might be used, from which the picture could be afterwards separated; but if waxed or rubber paper be used, I think it will be found necessary to give it a preliminary coating of collodion. Alumed gelatine would, doubtless, make a very good surface for albuminizing; but the print in that case could not be separated from the paper. The alumed gelatine would not exclude the silver, and would hold the hyposulphate as firmly as ordinary paper.

If I were to venture a suggestion in these circumstances, it would be merely to repeat what has been suggested before, that if anything like permanent silver printing is desired, albumen should be abandoned, and collodion substituted. Indeed, considering the ease with which collodio-chloride prints may be produced, and the facilities that exist for lifting them from the support on which they are prepared to another substance free from hypo or other contamination, and the beauty of the result, it appears to me surprising that this method of printing has not long ere now become much more common than it is, especially for small pictures. If I were to return to silver printing at all, this is the process which I would adopt. The extra expense of the collodion should hardly stand in the way, considering the rapidity with which the prints might be finished; and even should a small additional charge be necessary for such prints, it is nevertheless likely that they would commend themselves to the general public if good specimens were shown.

I lately saw some prints of this description produced by a firm in this town, superior in delicacy and tone to the generality of silver prints, and, no doubt, superior in permanency. These were produced by ordinary negative collodion, and transferred to albuminized paper; but I should imagine that alumed gelatine would be a safer coating for the transfer paper than albumen. It would also be more suitable for the application of any protecting varnish.

Bridgend, Perth, March 31, 1871.

REDUCTION OF NITRATE OF SILVER BY CHARCOAL.

BY C. E. CHANDLER.*

WHEN solid nitrate of silver, either in crystals or sticks, is placed upon glowing charcoal, deflagration takes place, the silver being left in the metallic state, while binoxide of nitrogen and carbonic acid are evolved. The nitrate is fused by the heat of the reaction, and sinks into the pores of the charcoal, and as each particle of charcoal is replaced by metallic silver, the structure of the original wood is preserved. With proper management, pieces of silver of any desired size can be prepared, showing the exact structure of the wood. A crystal of nitrate is placed on the end of a piece of charcoal, and the blowpipe flame is directed upon the coal near the crystal to start the reaction. When deflagration begins, crystal after crystal may be added. The nitrate fuses, passes down through the porous metal already reduced until it reaches the glowing coal, where it is reduced. I have prepared in this manner lumps of silver weighing an ounce or more, which exhibit most beautifully the rings of the wood.

THE PREPARATION OF COLLODIO-CHLORIDE OF SILVER.

BY JULIUS KRUGER.†

I HAVE compared the many and various formulæ which have been given for the preparation of this description of collodion, and am convinced that the cause why this material so very suitable for many purposes, is employed to so limited a degree, is simply because one is generally brought to a standstill at the first unsuccessful result obtained. For this reason, a process which is certainly deserving of much better treatment has frequently been abandoned, and, on this account, I have resolved to come forward once more to point out the manner of proceeding which has ensured me the best results.

I.—THE NORMAL COLLODION.

If, under ordinary circumstances, particular attention is necessary in the selection of a proper description of pyroxyline, precautions are doubly necessary when the gun-cotton is required for the preparation of collodion for the purpose under discussion. It is not enough that the gun-cotton should be capable of entire dissolution, but it is particularly necessary that the film, when removed from the glass, should be of an exceedingly uniform character, without any unevenness, and of peculiar elasticity. It must not possess the hardness of parchment, but should appear more like a piece of human skin.

As I have been able to prove, by recent experimental results, the chemical nature of the iodine and bromine salts are of very notable influence upon the consistence of the collodion film, and, for this reason, it is important to pay particular attention to them.

One great evil of normal collodion lies in its disposition to contract and to split away from any surface to which it may have been transferred—as, for instance, paper, metal, porcelain, and the like—when subjected to slight friction, on which account transferred positives are, as a rule, soon destroyed or injured. All risk of damage of this kind is, however, avoided by the institution of certain modifications.

Castor oil, which has been recommended for the purpose, does not possess the necessary advantages, but, on the contrary, gives rise to further defects. It does not dry, and, therefore, imparts to the collodion a certain degree of toughness; but, from the fact that the oil hermetically locks up the ether and alcohol atoms, the collodion remains for a long time gelatinous, and never yields a brilliant film. On close inspection, the film is invariably opalescent, and occasionally there will be found iridescent markings upon its surface. Moreover, a durable elasticity is not imparted to

the collodion by the presence of the oil, and a pure film of normal collodion will be found much more permanent than one containing castor oil. For these reasons, therefore, the addition of castor oil to the collodion cannot be recommended. It is true, the quantity of oil added may be reduced to a minimum, and the defects thus, to a certain degree, obviated; but I have found that when the collodion contains but two to four drops of oil per pound, the result is quite inappreciable.

On this account, I made search for another material which should possess the requisite advantages without being saddled with the defects inherent to castor oil. The most promising appeared to me to be glycerine; but, although this was capable of imparting pliability to the collodion, it disappeared altogether from the film as soon as this was placed in water or any solution of an aqueous character. It is, therefore, a deception to think that glycerine renders collodion more tough and durable. Irrespective of its easy solubility, it has, in fact, no other influence upon the dry collodion film beyond that of rendering the same more porous, and, for this reason, might be of benefit in dry processes. Pure glycerine is, therefore, as we see, less suitable to our purpose than castor oil.

There remained nothing but to discover a compound which should unite in itself the two qualities of elasticity and durability, together with a certain capacity to resist external influences from friction, &c. An addition of some of the colourless gum resins struck me as suitable, and indeed, as far as my experience has gone, I am in a position to recommend this modification of the collodion. The gum resin must never be employed alone, but always in conjunction with glycerine or castor oil, for every description of resin renders the dry film hard and brittle, so that removal from the glass becomes almost impossible; and this latter point is one of great importance, for upon it depends almost entirely the success of the whole process.

Further experiments were made with linseed oil, linseed oil varnish, copai-balsam, and Venetian turpentine. All of these materials have suitable qualifications, and are well fitted for the purpose, but my researches have not yet sufficiently progressed to enable me to point out the one best adapted for use in this connection. At any rate, I would recommend their trial by experienced photographers.

I will now proceed to describe the manner of preparing the collodion.

II.—COLLODION WITH RESIN, GLYCERINE, AND CASTOR OIL.

To manufacture one pound of normal collodion take:—

Alcohol ..	$\frac{1}{2}$ pound or	180 grammes
Ether ...	$\frac{1}{2}$ " or	180 "
Pyroxyline	85 to 90 grains or	5.03 to 5.5 "

Add to this, of the resin compound, 12 to 16 grains, or from 72 to 100 centigrammes, or, in lieu, a like proportion of linseed oil, turpentine, &c.

The resin compound is prepared separately by mixing together the following:—

Castor oil	1 part
Glycerine	4 parts
Gum sandarac dissolved in absolute alcohol	2 "

The proportions for the preparation of the last-named are, 1 part of gum to 3 parts of alcohol.

Before I add to this collodion the chlorides or nitrate of silver, I test it in regard to its cohesive qualities, its consistence, and its capacity for leaving the glass, taking care to remember that the prepared collodio-chloride is apt to lose some of these qualities in a certain degree. By altering in one way or another the proportion of the components, such as the normal collodion, pyroxyline, and the alcohol and resin mixture, it is easy to secure the required qualities, it being often found desirable to add to the prepared collodion a few drops of linseed oil.

The collodion, after standing for some eight days in a moderately warm locality, is carefully decanted and weighed. If the pyroxyline was of good quality, but very little residue

* American Chemist.

† Licht.

will be found, which can either be thrown away, or mixed with a little alcohol-ether mixture and filtered again, the same being added to the previously decanted collodion.

For every pound of normal collodion should now be added:—

Chloride of calcium 3.25 grammes
Chloride of magnesium ... 1.25 ..

the above being in the first place ground to a fine powder, and dissolved in an ounce of alcohol.

When introduced into the collodion the latter should remain unchanged; it is well after considerable agitation to allow the mixture to stand for twenty-four hours.

Meanwhile 200 grains or 11.25 grammes of nitrate of silver are finely powdered, and 10 drops of pure nitric acid added to the same; gradually half an ounce of dilute alcohol (half water and half alcohol) is also added.

The mortar, if necessary, is warmed in order to facilitate the solution of the nitrate of silver, and the latter is then added to the collodion. Thorough agitation of the mixture is now imperatively necessary, but the operation, as also that of mixing in the silver, should be conducted in obscurity. The shaking of the liquid may be carried on for an hour, and at the end of this time 30 to 40 drops of a saturated solution of pure citric acid are added.

In this manner is the collodio-chloride prepared, and as regards the best method of employing it I will say a few words on a future occasion.

The quantity of nitrate of silver specified for addition to the collodion is in no way an arbitrary one, but is calculated upon the equivalent numbers of each of the bodies employed. Eighty parts by weight of the chloride salts require 155.65 parts by weight of nitrate of silver in order to be completely decomposed. But as a notable excess of free nitrate of silver is required in the mixture in order to ensure sufficient vigour and depth in the pictures, it is necessary that a further quantity of 44.35 grains be added.

To avoid the crystallizing out of this excess of nitrate of silver in the prepared collodion, it is necessary that the proportion of citric acid which has hitherto been recommended for use should be considerably diminished, which may be safely done in the presence of free nitric acid.

ON SOME NEW DERIVATIVES OF ALBUMEN.

BY O. LOEW.*

In regard to those derivatives or products of substitution of albumen, which stand nearly related to albumen, our knowledge is as yet very imperfect, and the principal radical complexes of the proximate constituents of albumen are not known at all. The difficulty of obtaining some insight into the composition of albumen is chiefly due to the facility with which albumen is split up, by different chemical agencies, into many simpler substances, as tyrosine, leucine, benzoic and caproic acids, or even uncrystallizable so-called extractive matters, of which it is difficult to obtain an exact chemical formula.

Some time ago I endeavoured to obtain products of substitution of albumen, and at last succeeded in forming several derivatives, among them a nitro-product hitherto unknown. As regards the action of fuming nitric acid upon albumen, we only know that the latter is oxidized to an acid, called by Mulder xanthoproteic acid, for which, however, no exact formula has been given. In my experiments, a mixture of one volume of fuming nitric and three volumes concentrated sulphuric acid were employed. If less of the latter was used, an oxidation, in addition to the substitution, would occur.

Thirty grms. of finely-powdered albumen were gradually added to a cool mixture of 90 c.c. fuming nitric acid and 270 c.c. concentrated sulphuric acid, shaking well after each addition, and taking care that the mixture remained cool. The albumen was slowly dissolved to a clear solution without

* Read before the Lyceum of Natural History of the City of New York.

any disengagement of vitrous acid fumes, and the solution, contained in a vessel surrounded by cold water, was, after a lapse of ten hours, poured into about fifteen times its volume of water. The voluminous flocculent precipitate resulting was immediately filtered, washed, lastly, with hot water, and dried with care. The quantity obtained amounted to nearly two-thirds of the albumen employed; another part of the albumen is converted into a soluble product, which, after neutralization of the acid filtrate, gives a precipitate with tannin.

The powder thus obtained is of a light-yellow colour and a slightly bitter taste. It is insoluble in water, dilute acids, and alcohol, but is soluble in dilute alkalies, forming a reddish solution. On heating these alkaline solutions, a decomposition begins, and new products are formed, which I have not thus far examined. On heating the powder in a dry test-tube, it behaves like the original albumen, empyreumatic vapours being developed, accompanied by cyanogen, and carbon remaining behind.

On analysis, this new derivative yielded the following figures:—

I. 0.680 grms. gave 0.144 barium sulphate (determined by Kolbe's method) = 2.92 per cent. sulphur.

II. 0.912 grms. gave 0.200 barium sulphate = 3.03 per cent. sulphur.

1. 0.269 grms. gave 2.40 c.c. nitrogen at 741.5 m.m. barometer, and 9° C. = 17.20 per cent. nitrogen.

II. 0.268 grms. gave 2.37 c.c. nitrogen at 742 m.m. barometer, and 9° C. = 17.00 per cent. nitrogen.

I. 0.366 grms. gave 0.184 grms. water and 0.594 grms. carbonic acid = 5.57 per cent. hydrogen and 44.26 per cent. carbon.

II. 0.380 grms. gave 0.184 grms. water and 0.614 grms. carbonic acid = 5.58 per cent. hydrogen and 44.01 per cent. carbon.

These figures correspond to an albumen in which 6 atoms of hydrogen are replaced by 6 atoms of the nitro-group, and 1 atom of hydrogen by 1 atom of the sulph-oxyl group. The generally adopted formula of albumen is:—

(Lieberkuhn has in his formula four more atoms of hydrogen.) The formula of the new derivatives is therefore:—

	Theory.	Experiment.	
		I.	II.
C ₇₂	864 ...	44.13 ...	44.01
H ₁₀₂	102 ...	5.21 ...	5.57 ...
S ₂	64 ...	3.27 ...	2.92 ...
N ₂₄	336 ...	17.16 ...	17.20 ...

The rational name of this compound is, therefore, hexanitro-albumen-sulphonic acid. We know two different classes of nitro-bodies; the one class yields, by treatment with reducing agents, the original substance, as nitro-cellulose and nitro-glycerine; the other class yields amidated products, as in the case of nitro-benzoic acid. The cause of this difference in behaviour is, that in the first case the hydrogen of an hydroxyl is replaced by the nitro-group, while in the second case the hydrogen in combination with the carbon is replaced by the nitro-group. To decide to which class the hexanitro-albumen-sulphonic acid belongs, it was treated with sulphide or ammonium, and a new amorphous body thus obtained, which bears no resemblance to albumen nor to albumen-sulphonic acid, which latter I shall describe below. This new body seems to combine with acids, as well as with bases, but does not appear to form any crystalline compounds. I intend to further study this body; it is possible that we have here the corresponding hexamido-albumen-sulphonic acid.

Another Derivative of Albumen with Concentrated Sulphuric Acid.—It is well known that albumen swells up considerably in concentrated sulphuric acid, but no investigation has been made as to what this product really is. I mixed in a mortar 1 part of albumen gradually with 10-15

parts of concentrated sulphuric acid, and allowed it to stand in the cold for one day; the mass was then treated with cold water till the free SO_4H_2 was all removed; the flocculent mass was placed in a dilute potassa solution (1 to 6-8), stirred sometimes, allowed to stand in the cold for one day, filtered, precipitated by acetic acid, the precipitate washed and dried. Analysis showed that it is albumen-sulphonic acid. It contains twice as much sulphur as the albumen itself, is insoluble in water, alcohol, and dilute acids, but soluble in alkalis, wherein it swells up considerably before the real solution slowly takes place. On boiling these solutions, decomposition takes place. I shall make further investigations on this subject.

◆

COFFEE AND OTHER DRY-PLATE PROCESSES,
WITH PRACTICAL DETAILS
OF A NEW DEVELOPER GIVING EASE AND CERTAINTY.
BY A. DE CONSTANT.*

§ VI. DESICCATION OF THE PLATES.

This operation may be considered as one of the most important manipulations connected with the preparation of dry plates. It is, I believe, the general custom to dry them in a closed box or chest, placed upon the floor in a corner of the laboratory, a vessel of hot water or some such apparatus being enclosed therein to accelerate the drying of the plates. In a mode of proceeding like this, there are several dangers to be feared which I will here enumerate:—

1. If one does not take care to change the filter-paper upon which the plates stand, at least twice, there is formed at the foot of them a pool of liquid which, more or less befouled by contact with the paper, is subsequently attracted up the sides of the plates as soon as these have dried, and produces stains and spots of various kinds, ordinarily of an elliptical shape, which, on the application of the development, are at once made apparent, and destroy some portion of the cliché.

2. The source of artificial heat introduced into a box of small dimensions, being too near the surface of the plates, precipitates the desiccation thereof in an unequal manner, acting more vigorously upon the lower portion than upon the upper.

3. The box being closed, the moisture escaping from the glass remains suspended in the enclosed atmosphere, and thus seriously retards the desiccation of the plates. To remedy this defect, M. Carey Lea, always an ingenious practician, proposed the introduction of a vessel of sulphuric acid (which largely absorbs moisture); but this makes matters more complicated, for the liquid is a disagreeable one to manipulate.

4. A last inconvenience of the closed box lies in the fact that, being placed upon the floor, it contains always a temperature of a sensibly different nature to that of the room, so that when a plate is taken out to be placed in the frame, the change of atmosphere produces upon the surface of the glass a slight vapour scarcely visible to the eye, but which is not the less persistent or dangerous. For if put into the frame in this condition, the vapour will materially interfere with the virtues of the plate, and cause partial, if not complete, insensitiveness, a circumstance one would scarcely attribute to so insignificant a cause.

To remedy these inconveniences, which a long experience has taught me to respect, I have adopted an arrangement which may be described as follows:—

The plate, coated and finished, is stood on end upon filter paper to drain, in the first instance, and then removed to the drying closet, where it rests upon a wood support cut almost to a knife edge. The plate is in a sloping position, with its back resting against a wooden peg or support, of which several are fitted to the back of the closet, four or five inches apart. In this way the moisture which runs towards the bottom of the plate is not arrested in any way,

but flows to the lower corner, where it is absorbed by a small band of filter paper placed there for the purpose. When the whole number of plates are finished, the draining papers are carefully removed, and the closet closed, a small shutter in the door being, at the same time, opened. This opening is covered with yellow calico to prevent all ingress of light, so that the moisture can readily escape, and a good equilibrium is maintained between the atmosphere in the closet and that in the dark room. If I have the room warmed, as is usually the case, a slight current of warm air is in this way established in the closet, and the plates dry gently and uniformly without any serious change of atmosphere or the possibility of injury when transferred to the printing-frame.

It should always be borne in mind never to place a plate in the frame without previously examining it in a horizontal position. If the surface is very brilliant (like that of glass), and exhibits, by transparence, no trace of fog or stain, the plate may be put into the dark slide with implicit confidence. If at all troubled with a cloudy aspect, it is best to warm the plate before a hot iron surface until it reassumes its brilliant aspect.

In drying, the plates generally become of a very transparent nature, which is, indeed, one of the inconveniences of the dry process, reflections caused by the thickness of the glass being often caused on the exposure of the plate. To remedy this defect, it has been recommended to coat the back of the glass with a dark tint of some kind; but, apart from the inconvenience of this proceeding, the removal of the pigment is also a matter of some trouble, and for this reason I employ a piece of black matt paper, placed accurately at the back of the cliché. The brown tint imparted by the coffee serves also to mitigate the evil when proceeding, as in the tinting by a turnsol, as proposed by Mr. Lea.

§ VII.—EXPOSURE.

As I have already stated, dry plates prepared by the coffee-gum method require an exposure of but three times that necessary for the wet process, with the same lens and same light. In operating, it is desirable to understand thoroughly the capabilities of the lens with which one works, as likewise the effect of the diaphragms, and also to make a trial of a wet plate every time that a change is made in the collodion or the silver bath. As a rule, very short exposures should be avoided, for one is much more certain of a fine result by giving full exposure, because the development is thus facilitated, and it is always better to moderate rather than force the action of the developing solution.

Although it may appear somewhat paradoxical, I may state that a long exposure is more necessary during bright sunshine, from the presence of great contrasts, arising from the intensity of the shadows. I believe, indeed, that it is impossible to secure a fine landscape negative endowed with harmony and full effect of distance during full sunshine, although, from the fact of many of my brethren choosing very bright days for their work, it would appear that there are not many of my way of thinking.

§ VIII.—THE DEVELOPMENT.

As a general rule, I believe it to be the best plan to develop one's plate immediately. The operator is generally anxious to know at once the nature of his result, and it is very seldom indeed, even on a distant tour, that arrangements cannot be made to proceed with the development. At the same time, it may always happen that the postponement of this operation is indispensable, and it is therefore always well to employ a process which allows of such a proceeding. With the coffee-gum method I have made but few experiments on this point, but it may be safely taken for granted that no inconvenience will be experienced when developing twenty-four hours after exposure.

In employing the alkaline development I do not use bromide of potassium, and I moreover alter the order of application with the ammoniacal solution, commencing my operations with that agent *à l'one*. After all that has been

* Continued from p. 153.

written on this matter, my mode of proceeding may appear an extraordinary one, but I have a very good excuse for it, in the fact that my results are always excellent, and, therefore, I follow no other plan. I will describe in a few words my method of proceeding.

The exposed plate having been covered with rain-water, or immersed for three or four minutes in a bath of that liquid, is drained and placed in a horizontal position; over it is then poured sufficient distilled water to cover the plate to which six to ten drops of a saturated solution of carbonate of ammonia have been added. This liquid, which is kept upon the plate and moved to and fro over the surface, restores to the dry film its original permeability, and commences, indeed, the action of development, for, if sufficiently exposed, the sky and high lights begin forthwith to appear. If the exposure has been too short, the effect is hardly, if at all, visible; but the operator need not despair on this account, for with a little time and patience it is possible, with the aid of the agents I shall indicate, to triumph over the most obstinate development. In any case, as soon as the aqueous solution of ammonia ceases to act upon the film, it is poured back into the developing glass, and a few drops (from one to three, according to the progress of development) of pyrogallie acid dissolved in alcohol are added; this pyrogallie solution is prepared by simply dissolving six grammes of pyrogallie acid in one ounce of alcohol. The mixture is not poured upon the plate from one spot, but applied over the whole of the surface at once, as the effect is frequently so rapid that spots or stains are otherwise produced.

The image now fully appears, but it is seen only by reflected light, and is scarcely visible when the plate is viewed as a transparency. Nevertheless, the action of the solution is continued until every possible detail in the shadows has been brought out. You can scarcely develop too much, for it is these details which give rise to the half-tones, and produce that harmony and softness which impart so much charm to the picture. I have also been successful in elaborating a means of completing, or even forcing, the development if necessary, in the case of under-exposure; this method, which is a new one, consists in using a solution of iron after the application of the alkaline pyrogallie developer. Many experiments were necessary before I was able to fix upon the elements and proportions of the same for this novel developing agent, and at last I have determined upon the following formula:—

Water	100 cub. cents.
Ammonia-sulphate of iron ...	3 grammes
Sulphate of copper	3 „
Citric acid	3 „

This compound, which may be preserved pure and in good condition for a very considerable period, is poured upon the well washed plate, and sometimes produces by itself sufficient action. Generally, however, it is necessary to complete its action by adding a little silver, when details will at once appear, which otherwise would never have been brought to light; and it is, indeed, but very rarely that with the aid of this solution a satisfactory result is not attained, even in very unpromising instances. The negatives treated in this manner become more opaque, and assume in general the ordinary grey tint of wet plates, instead of the brownish red colour usually possessed by them. In every case a more or less complete intensification is necessary. I do this with an ordinary citric and pyrogallie solution thus compounded:

Water	300 cub. cents.
Pyrogallie acid	2 grammes
Citric acid	1 gramme

This mixture is in the first place applied alone to the plate, and subsequently one or two drops of a three per cent. silver solution are added to the solution.

This intensification must be conducted with very great precaution, for it is difficult to judge of its effect, and frequently the action is allowed to go too far. The image soon acquires vigour, while preserving its softness and trans-

parency. At the same time there are some descriptions of collodion (very excellent for general use), which, when exposed to the sun or very bright light, soon become solarized, and are thus incapable of attaining sufficient vigour, and when finished are possessed of a dull rose colour. As negatives of this kind print very badly, the operation of intensifying must be stopped and postponed until after the plate has been fixed, care being taken to wash thoroughly between the two manipulations. In this way the details of the image are rapidly brought out, and the negative passes from a rose colour to that of a dark purple, a very favourable tint for printing purposes.

This last method of intensifying requires at least as much care as the preceding one, and it is necessary forthwith to pass the plate into the hyposulphite bath. In following the directions I have indicated, the operator has at his disposal a series of methods by means of which, with a little skill and discretion, he will be enabled almost invariably to secure a satisfactory result.

I cannot leave this subject without a recommendation to the operator as to the way of manipulating the plate during development. He should never hold the negatives in his fingers, as the result is always injured corners or dirty spots. The pneumatic holder being inconvenient to use in this case, it may be acceptable to know of another kind of plate-holder, which I have found very useful, and which I had in the first place from the brother of M. Braun. This instrument is light, always clean, serves for plates of all sizes, is strong, and, moreover, costs but little. I here give a sketch of it.

This very light instrument is made of hard wood; it is studded with notches or pegs corresponding with the sizes of the plates, which are thereby fixed upon the rest. The developing liquid can be made to flow over the whole surface of the plate very readily, and the ends of the negative being free, the solution is easily poured back into the developing cup.

In recommending the operator to commence the development with the ammoniacal solution in a cup or glass, I have sought to simplify, as much as possible, the necessary utensils; but when working in the laboratory, I think it is better to add the ammonia at once to the water bath in which the plate is first immersed for moistening the film, as the preliminary operation is thus carried out with more uniformity, and the subsequent developing action rendered more active. As a matter of course, in this case it is necessary to add the ammonia in a suitable proportion to the quantity of water contained in the bath—say about thirty or forty drops of ammonia to a utensil of ordinary size. If, as I have before said, the exposure has been well-timed, the high lights will be already rendered visible by this treatment, and the plate is then placed upon the support above-mentioned, and the development continued with some more ammoniacal water, to which a few drops of pyrogallie acid solution have been added as previously described.

(To be continued.)

UPON THE SENSITIVENESS TO LIGHT OF IODIDE, BROMIDE, AND CHLORIDE OF SILVER.

BY DR. SCHULTZ SELLACK.*

THE photographic sensitiveness of the several salts of silver, respecting which some very contradictory opinions have been given, may be separated into qualitative and quantitative sensitiveness. Under the former kind is understood the capacity of the sensitive film to be im-

* Photographische Mittheilungen.

pressed by various colours; while quantitative sensitiveness denotes the degree of impression by any particular colour. If, as is usual in practice, one has to do with many colours at one time, that salt would be considered the most sensitive which reproduces the greatest number of tints, and which is, therefore, the most qualitatively sensitive. In cases, however—as in portraiture—where shortness of exposure is the principal point to be considered, quantitative sensitiveness, even at the loss of qualitative, is preferred. For portrait photographers, therefore, a qualitative—but, above all, a quantitative—silver salt is the best; while, on the contrary, to meet photographic requirements in the reproduction of oil-paintings, where the exposure may be prolonged, a qualitative material would be the more suitable. Finally, in the copying of engravings, the qualitative sensitiveness of a salt is limited, for it is, in this case, a question merely of reproducing the direct contrast of black upon a white ground.

The qualitative sensitiveness or compass of sensitiveness possessed by the different silver salts for colours cannot be ascertained by photographing a series of tints painted upon a board, from the fact that there is no pigment in existence of a pure character, regarded from a scientific point of view. Dr. Vogel has shown that many colours which differ from each other but very slightly when seen by the naked eye, yield remarkably diverse results in photography. Some red colouring matters—as, for instance, zinnabar—contain yellow, or, like carmine, blue; and, in these cases, the photographic action would be widely different, seeing that yellow is without scarcely any action upon the sensitive film, while blue attacks it very vigorously. Pure colours may be obtained by observing a beam of white light through a glass prism. These rainbow tints—or spectrum, as it is termed—show certain lines running across the colours, which have been designated by certain letters, and mark the limits of the colours. These lines are always to be seen in a photograph of the spectrum. Red and yellow in the spectrum do not exert any photographic action; green reaches from line E to line F; blue, from F to G; violet, from G to H. Beyond H the spectrum is invisible, but, nevertheless, acts upon a sensitive photographic film.

A chloride of silver plate prepared in a fresh silver bath free from iodine yields a picture only of the invisible portion of the spectrum, and of the outside half of the violet, near line H.

An iodide of silver plate yields a picture which includes from the invisible rays to beyond G, as also the violet and a small portion of the blue.

A bromide of silver plate prepared in a fresh silver bath free from iodine (from an ordinary silver bath containing iodine there is invariably produced, even with pure bromized collodion, a bromo-iodine salt), gives a picture of the invisible part of the spectrum, from violet to blue, in the neighbourhood of F.

An iodo-bromized plate gives a picture of the spectrum reaching from the end of violet to line E, and includes, therefore, the green portion of the spectrum.

An iodo-chlorized plate also yields an image which takes in green.

The chloride of silver plate is, when viewed as a transparency, very slightly coloured, and appears of a blue tint by reflected light. Bromide of silver is of a light yellow by transmitted light, otherwise, also, of a bluish colour. Iodide of silver is of a whitish yellow; and bromo iodide of a darker yellow.

As regards qualitative sensitiveness, therefore, iodo-bromide of silver ranks first, then follows iodo-chloride of silver, pure bromide of silver, iodide of silver, and, lastly, chloride of silver. The same results are obtained if the sensitive plate is prepared from nitrate of silver collodion, and treated in an iodide, bromide, or chloride of potassium bath, and washed; the iodide of silver plate is sensitive, and precisely the same description of pictures of the

spectrum are obtained as when an excess of silver salt is present. The quantitative sensitiveness of these plates is, however, less; an iodide of silver plate prepared in this way, for instance, requires an exposure ten or twenty times as long as one produced in the ordinary manner. The so-called sensitizers are, in wet plates, without any influence; acids have no action whatever upon the qualitative sensitiveness of a plate, while, as is well known, they materially diminish quantitative sensitiveness. Dry plates possess the same qualitative sensitiveness as wet plates, but the quantitative action of the former, as we know, is somewhat less than the latter. The presence of fluorine in the silver bath is without influence upon the qualitative sensitiveness.

For the purpose of obtaining comparative results in regard to quantitative sensitiveness, the same normal collodion was treated respectively with salts of iodine, bromine, and chlorine in such a manner that the same amount of silver salt was formed upon each plate.

Chloride is less sensitive to the invisible parts of the spectrum than bromide of silver, and this, again, less sensitive than iodide of silver. Pure chloride of silver does not, therefore, find employment in the negative process.

As regards the violet portion of the spectrum, iodide of silver is much more sensitive than bromide of silver, iodo-bromide of silver being, according to the amount of bromine contained, less sensitive in this respect than pure iodide of silver.

For the blue, from line G to F, is iodo-bromide of silver, which contains at least one-fourth bromide, more sensitive than bromide of silver; the action of the blue is, however, much more feeble than that of the violet.

For green, from line F to E, iodo-bromide of silver only is impressionable; iodo-chloride of silver behaves in the same way as iodo bromide of silver, but is, as a rule, less sensitive.

The larger compass of sensitiveness of the compounds of iodide of silver with bromide and chloride of silver was already known in the days of Daguerreotype, and the pure iodide of silver employed, in the first instance, by Daguerre, was very soon abandoned for these compounds. The qualitative sensitiveness of iodo-bromide of silver in the Daguerreotype process is, as Draper's early experiments proved, exactly the same as in the wet process, and my own researches have proved the same to be the case with iodide of silver.

From the above data some very important deductions may be made of practical value. For a quick-working collodion, giving details in the shadows—or, in other words, in those parts illuminated to a greater degree with yellow light—a material treated with iodo bromide salts, and containing a larger proportion of iodide, would be preferred, which, therefore, reproduces violet much more energetically than blue or green.

When, however, it is desired to secure a picture of very harmonious character, then an excess of bromide is to be preferred; blue and green light is then reproduced in the same degree as in the previous instance, while the action of the violet is less energetic than in the previous instance.

The quantitative sensitiveness may be increased to a certain degree, by increasing the thickness of the film, either by the pressure, therefore, of more iodizing solution, or by a thicker collodion. This influence is more remarkable with a bromine salt than with an iodide.

Actinic light invariably passes through the sensitive plate, as Onumerganck was the first to show by placing behind the first plate a second one, upon which an image was obtainable. It is an absurd proceeding, therefore, to blacken the back of the plate for the purpose of making use of this light, as is recommended in dry-plate photography, for it is immaterial whether the light passing through is absorbed by this black pigment, or by the blackened wall of the dark slide. If the experiment of

Ommergauck is repeated with ordinary iodide of silver plates, in the faint image upon the second plate will be found the details of the shadows very much pronounced. This may be explained in the following manner:—If the spectrum is photographed with two plates in the way mentioned, upon the rear plate is obtained only the depiction of the green and blue, and not the violet; while, upon the front plate, the violet is by far the most apparent.

If a thin film of metallic silver is produced upon glass, and iodized in the same manner as a Daguerreotype plate, a very thin clear film of iodide of silver is obtained, of a slight yellowish tint. This film, like the sensitive collodion plate, does not allow the violet of the spectrum to pass, but permits of the green and blue rays doing so without lessening their energy. It would be possible, therefore, by producing a film of iodide of silver of this description upon one of the surfaces of the lens, to modify, or even annihilate, the action of the violet rays. This is a point deserving of elaboration and experiment, for a method of this kind would be invaluable for the reproduction of paintings.

The peculiar behaviour of the iodide of silver by this absorption of light, as also that of fused chloride and bromide of silver, and the compounds of iodide of silver, are of very great scientific interest, and have already been discussed by me in a communication to the Academy of Sciences.

As regards the invisible chemical change of silver salts by light, it may be mentioned that the action upon chloride of silver (the only salt used in practice) occurs only in the ultra-violet and invisible portion of the spectrum, as already demonstrated by Becquerel. This chemical change is, therefore, identical with the photographic sensitiveness of the chloride of silver; and it is probably the same with bromide and iodide of silver. How the action behaves quantitatively cannot be measured by chemical means. Because chloride of silver darkens the most in light, it by no means follows that it is decomposed more vigorously than the other salts; perhaps the product of decomposition is more deeply coloured than those of bromide and iodide of silver.

With collodion plates prepared in a suitable manner with other silver salts—as cyanide of silver, sulphocyanide of silver, oxalate of silver—no trace of photographic action could be observed.

The above experiments were carried out in Dr. Vogel's photographic laboratory at the Berlin Industrial College; and to Dr. Vogel, therefore, I tender my most sincere thanks for his courtesy.

PHOTOGRAPHIC RESIDUES.

A GREAT deal has been printed in the photographic journals about the saving of waste of our precious metals in the various processes of photography. Many of these are good, many are scientific and elaborate; but what the photographer wants, so far as I can see, is, how to save his waste—be it ever so small or great—in a simple manner, and convert it into cash, or new material to use again. So many methods of saving wastes have been printed, that I will not take up your valuable space on that matter, but will now begin with a practical method of reducing such as the chlorides, by salt from old nitrate of silver baths (this ought to give about 75 per cent. of silver), cuttings of silver prints, hypo fixing baths, and developing solutions. All should be saved, and the dirt residue, or settlement, dried. Now comes the practical part that all careful photographers should take note of: first, don't give your savings to any one to convert for you; the chances are, they will reduce it, and keep the remainder for their honesty. I recommend the American photographer to reduce his own wastes, as he possesses, or his neighbour does, the chief apparatus, that

is, a globe stove or furnace. In England there are none, so one must be built for the purpose.

The following method for reducing silver waste was given me by a gentleman who came to learn photography for his amusement, he having retired from a successful business in London as a gold and silver refiner. "Now," said he, "as you have so openly shown me the secrets of photography, I shall only be too pleased to show you the few secrets of our trade, so far as they concern you." Then he told me that secret—black flux—and bidding me to make what use of it I liked. As he freely gave it to me, so I freely give it to your readers.

The converting process is as follows:—Say you have one pound of silver waste; take one pound of pearlash, two pounds of common salt; mix them well together by sifting through a sieve, or otherwise; place the whole in a crucible of clay, not blacklead or plumbago. Now see to the stove. Place on the middle of the grate half a brick, or, still better, the bottom of an old crucible, bottom upward, as a table to stand your crucible on; make up a little fire round this; then put in your crucible, surrounding it with fuel; place a cover or large lump of coke on top; get your heat up, and, when all is apparently in a liquid state in the crucible, add more of the waste, if there be any, as a crucible first filled will bear to be refilled two or three times; give more time in the fire; stir it with an iron rod, or, if the fuel has dropped into the pot, dip out with an iron ladle. All the silver ought to sink to the bottom of the crucible in the shape of a button, large or small, as the case may be. Now see all safe, and go to bed, or let the whole remain till the fire is out; but if you feel as I did when I began, and want to know the result, get a pair of smith's tongs, and remove the crucible from the fire, not on to the hearth, say, but into a pail of water, and the result will be, the whole household will have a vapour bath gratis. When cold, break off the bottom from pot, and there is the precious metal in one solid button, if properly fused. The tools required are a few clay crucibles, a pair of smith's tongs, a small iron ladle one and a-half inches, with a hole in the bottom for the metal to drain through. Sometimes the crucible will break in the fire: save everything, ashes and all, and wash by shaking in a pan of water. The metal will be found at the bottom, to be remelted. As a precaution against accidents, some fire-clay, mixed with cow-dung, is made into a stiff dough, a lump put on a piece of strong paper, the filled crucible pressed into the dough, and the paper, &c., brought up round the sides to about one-third its height; this forms a second crucible on the lower part, and is a great protection to the first one. Another plan is, to place the crucible mouth downward on a moderate fire before filling. Metallic gold or silver can be melted without flux, and a plumbago pot used, which will do for many times; but with a clay crucible and flux you require a new one each time. I use ordinary gas-coke, but think anthracite coal would be just as good. In getting up your heat, cover the pot some inches deep in fuel. Don't be afraid if a little gets in, as it will swim, and can be easily taken out with the small ladle. The metal will run through the small hole in the bottom of ladle, should you skim any with the dirt.—H. D. F., in *Anthony's Bulletin*.

HOW TO ENAMEL MOUNTED PHOTOGRAPHS.

BY L. G. KLEFFEL.*

THE favour lately bestowed by the public upon pictures of this kind renders it desirable that an easy and reliable method of preparing them be in the possession of all photographers. The following plan, already practised in America, has been recommended to me by many friends, and has some pretensions to the above-mentioned qualifications:—

* *Licht*.

The plates used for the purpose must be perfectly free from scratches, and quite even; they are best of plate-glass, which must be carefully cleaned, to allow of the film of collodion readily leaving the surface. To make certain that this takes place, a solution of white wax in turpentine, equal proportions of both, is applied to the better surface of the two, the compound being afterwards removed as perfectly as possible by means of a pad of linen, which is rubbed over with considerable energy. Treatment of the plate with talc is also recommended for the same purpose.

Cartes-de-visite cannot be well enamelled singly, and, for this reason, plates measuring about 9 inches by 11 are chosen, which are large enough to take six cartes at a time. The cardboard employed, which should not be too thick, must be cut somewhat smaller than the plate.

The pictures are cut of the same size as an ordinary carte-de-visite, so that when the cardboard is finally cut up, they cover the whole card.

A long strip of linen of the same breadth as the cardboard is moistened in water, and then gently wrung; upon one end of the linen is placed a glass plate of sufficient size, and on this a piece of cardboard measuring 9 by 11 inches (upon one side of which the name of the firm may be printed), face uppermost; upon this card is laid another, face to face, and the linen then folded over, the operation being proceeded with until the cards have been all enclosed in the moistened fabric, two cards always lying between two layers of linen. Finally, another glass plate is laid on the top, and the whole pressed down by means of a ten-pound weight.

The glass plate destined for enamelling is coated with a very transparent and tough collodion film in the ordinary manner, and allowed to dry.

The mounting of the pictures must be effected with a not too thin solution of gum arabic. Before the operation, the prints should be moistened, either by being placed in a moist cloth, or exposed to the vapour of hot water.

When the pictures have been mounted upon the moist cards, the latter are again enveloped in the linen, so as not to become too dry.

The gelatine solution used for glazing is prepared in the following manner:—

White gelatine of the best quality is cut into pieces and placed in water, in the proportion of one ounce of gelatine to fifteen or twenty ounces of water; after standing for a few hours, the vessel containing the solution is placed in an outer utensil of water, and warmed until the whole of the gelatine is dissolved; then the solution is filtered through moist flannel, and maintained at a temperature of about 30° Reaumur, or 100° Fah., until required for use.

To apply the gelatine coating, the plate coated with collodion is placed upon filter-paper, collodion side uppermost, and a sheet of the moist cardboard upon which the pictures have been mounted is taken from the moistened bundle, and laid, face downwards, upon the collodion surface. A strip of thick card about three-quarters of an inch thick is then placed upon the lower edge, and fixed to the plate, together with the picture, by means of some wooden clips. When this has been effected, the upper end of the cardboard is raised and bent back with one hand, while, with the other, a quantity of the gelatine is poured across the plate, beginning at the bottom; a small roller covered with filter-paper or cloth is then passed over the cardboard, beginning at the bottom of the plate, and, in this way, the superfluous gelatine is pressed out; after this has been done, the clips are removed, and the same operation repeated from the lower end. A stout glass rod will do for pressing out the superfluous gelatine instead of a roller.

These operations finished, another glass plate is laid upon the one bearing the pictures, and heavily weighted; in this condition the prints are allowed to dry. After twenty-four hours they will be in a position to be removed from the plate, this being effected by cutting through the card to the

glass with a sharp knife, and lifting the whole from the surface.

Air-bubbles are apt to form in the gelatine before drying if the liquid material happens to be too thick or warm, or the pressure of the roller is not strong enough; after drying, bubbles will also appear if the gelatine is too thin and hot, and the pressure exerted has been too great.

If the cardboard refuses to leave the glass, the collodion was either not sufficiently tough, or the plates were not perfectly clean.

To enamel single pictures it is best to proceed in the following manner:—

The plates are first coated with normal collodion, and afterwards with gelatine solution of one in twenty strength. The pictures, in this instance, must also be cut of the same size as the cardboard upon which they are mounted. The mounted pictures are dipped into cold water; the plate prepared with collodion and gelatine is then placed in a vessel of water, and a soft brush passed over the surface to remove the air-bubbles; the picture is placed upon the plate, under water, and both are then lifted out, drained, and placed under some sheets of filter-paper and a paper-weight to dry. Another way is to dip the pictures in a gelatine solution, and then to place them in contact with the collodionized plate. Any air-bubbles are removed by subsequent rubbing down with the thumb-nail, or in any similar manner.

To produce pictures with white or black borders, a piece of sensitized and blackened paper, of the size of a carte-de-visite, is ovalled out so as to form two masks. According as a black or white margin is required, either the picture itself, or the border of the same, is covered up by one of these black masks. Thus, if the picture is required with a black border, the print is produced in the ordinary manner, and, when sufficiently deep in colour, is covered with the black oval, and exposed again to the action of the light; if a white margin is desired, the open oval mask is at once put over the negative in the printing-frame.

ON TAKING BABIES.

BY ROLAND VANWEIKE.

MR ROLAND VANWEIKE, in our Philadelphia contemporary, instructs his pupil in the best mode of dealing with babies. He says:—

“The baby is a peculiar subject, and its little individualities and freaks of temperament need to be studied and humoured as much as in older persons.

“There are some photographers who won't make pictures of babies at all; at least, I have heard of those who did not, and I know they were not successful in the business. The baby is often the key that unlocks the purse for the whole family, to the benefit of the photographer. Besides, operating with them is a good school for self-government; it gives a man an opportunity to practise keeping his temper—for, of course, no man would get into a passion with a child—and as patience is, or should be, part of a photographer's profession, nothing, perhaps, will make him exercise this virtue more than making pictures of children. I have become satisfied, however, that one of the best means to help one to understand their dispositions and work into their good graces is to have some of the little pets—I don't mean pests—of his own in his own home. But you need not be discouraged, Focus; there's time enough for you yet, and a love for children is, after all, the great thing necessary to operating with them successfully. A kind word or look impresses itself upon the tender, sensitive nature of the child, and you oftentimes gain its confidence at once.

“We may be perplexed with business, or have more serious matters occupy our minds, but when it comes to this, we must, for the time being, come down to the child; we must forget all other things, and enter, as far as possible, into sympathy with this little sprig of humanity before us.

“If you do not succeed with one trial, try again, and continue to try so long as there is any possibility of success. If the child is neither frightened, cross, nor tired, keep your temper and persevere. If you cannot get it one way, try another; your success will depend much upon your resources, as well as

your patience; and when, after failing again and again, the fifth, sixth, eighth, or dozenth trial, you succeed, you feel amply repaid for all your efforts.

Focus. "The baby is ready.

VAN WEIKE. "Very well, we will proceed. This being a little one, we will sit it in this chair. The arms prevent its falling over, and as it rests against the back, we do away with the necessity of using the head-rest. The rest, however, is almost useless with small children, as it is very difficult to get them to keep the head against it. A smaller chair than this even, might be better, as some of the subjects are so small that there seems to be more chair than child. But it won't do to be too fastidious in this respect, for whatever means we employ to catch a perfect impression of the little one with the greatest certainty will insure us the greatest success. This little fellow seems to have been somewhat out of sorts this morning, but appears to be feeling better now, and if we proceed gently with him there will be no trouble. Be very careful about making any sudden noise, or having any loud talk or calling. Let the mother stand near him, so as to be out of the picture, and he will not be so likely to be frightened. We must work lively, Focus, with these subjects; see that he rests against the chair, get your focus, adjust your plate, fix his attention with some toy that has motion without being noisy, and make your exposure.

"The next is a child just can toddle, with a doll almost as large as she is, and a poodle dog. They want the child standing, with the doll and poodle in some pretty position. The doll may do, but the poodle never, especially such an animal as that, that is never still the tenth part of a second unless asleep. The only way in cases of this kind is to say firmly and decidedly, if they want a good picture of the child the dog must be left out, unless you have nothing else to do but experiment.

"Now here are the mother, father, grandmother, and, I presume, old maiden aunt, and there's a perfect Babel; we shall be bewildered, if the child is not. The first thing to be done is to send out all but the mother, and then see what we can do.

Focus. "She's afraid of me. She seems to be afraid of everything. We can't get her standing.

VAN WEIKE. "Now this is a case that requires peculiar treatment. We must gain her confidence and get her interested. Examine and praise her hoots, the locket on her neck, the ring on her finger, her doll, its dress, feet, and everything about it, and, finally, propose to make dolly's picture. She seems suspicious no longer, but readily assents to the suggestion. Now, the matter of making her picture must not be hinted, but everything that's done is for dolly. She is perfectly willing to sit with dolly to keep her still, and even consents to having her own head against the rest, when told it is necessary to get a good picture of dolly. We will show dolly this little singing bird, and our shy little miss has a good picture without her knowledge or suspicion. It is not often necessary to resort to as much strategy as in this case, but I have found it well always to keep the child's attention as much as possible away from what you are doing; say nothing about taking its picture.

Focus. "What do you do when the child won't have its picture taken? Here's one says she won't."

VAN WEIKE. "Well, she's probably been told about it over and over; and in the meantime, perhaps, has been to the dentist, or been frightened somewhere. She seems a sweet little girl, and not much afraid. I think I can soon get acquainted with her. I take her in my arms and carry her about the room, show her the pictures and playthings, with kind words and a few kisses, and now I think we may try a sitting. No, she won't sit. No amount of coaxing or persuasion will avail. She is good enough anywhere else but near that chair. Her mother gets out of patience, and threatens to whip her. Now this will never do; and the mother must be given to understand that threats or abuse will render it impossible for us ever to get a picture of her child. I can readily understand the style of treatment that child has at home, and what is the principle of government for the household. If we allow it to be practised here, this place will have as much terror for the little one as, no doubt, many others have. Love and kindness must rule the baby here. Compulsion is entirely out of the question, for even if the child should be compelled, through fear, to sit, we can readily imagine what kind of an expression such a state of mind would produce. No; if the child will not sit willingly, we must decline any further attempts at this time. We want her to go away with pleasant recollections of this

place, and next week, if she comes again to see our birdies, and all the pretty things we have, saying nothing about the picture, I have no doubt we shall succeed without difficulty.

"The next is a wide-awake youngster that don't care for anything. Now this type is generally as difficult to manage as any we have. He can only be kept in place in the chair by holding him, and he seems ready to explode at every noise or motion you make. Now there are two ways of fixing the attention of this kind: by keeping perfectly quiet, he watches for a few seconds, apparently waiting for something to turn up, and you can catch an impression; again, you may astonish him by the most violent demonstrations, bringing out your whole collection of birds and animals, and turning clown yourself.

"There is just as much difference in babies as there is in other folks; and, finding such a variety, we will not have time to go into details with them all, but will note some of the more prominent peculiarities. Those that we have no trouble with we need not dwell upon; but it is the difficult ones, or impossibles, that I want you to practise on. Now here is the baby only four weeks old, that don't take notice of anything, and you are expected to make a brilliant, wide-awake picture of it. Another, its mother says, is afraid of strangers, and won't let you come near it. She has no faculty for arranging its position or doing anything with it, so you must catch it as you can, arms and legs flying, making a perfect caricature on your idea of grace and propriety.

"This one wants three different sizes and styles of pictures, and when it comes to the trial we can't get anything.

"The next they want taken with the great red, freckled-faced nurse, because they think it would take better that way.

"Here's one just can walk; they want it standing. It won't stand still; it won't stay a moment where you put it. They don't want it sitting; its grandmother wants it standing, and if they cannot get it that way they don't want it. They've had it taken a great many times before, and never had any trouble. The only way is to prove to them, by trying, that the thing cannot be done, and then they may have it sitting, as it has always been done before.

"A youngster in a black velvet suit, the blackest of all black things to photograph."

Focus. "Why, I always thought black took best."

VAN WEIKE. "It does in some cases, but not for a child four years old, when it is often difficult to keep it still long enough for light drapery.

"Some measures ought to be taken to educate people in this direction, so they may not presume so much, but proceed from a knowledge of the facts in the case. We should lose no opportunity to impress upon customers the fact that light drapery is always best for children.

"A group of three children, from three to seven years old. Their mother wants them all standing side by side; thinks they would take better that way; as she 'intends to send the picture to Europe, she wants it taken good.'

"Now, when people come with such notions as these, we must try and persuade them out of them.

"Three children standing in a row!

"I don't want to make any such picture, much less to have it go to Europe as a specimen of American photography. By showing the mother the absurdity of such an arrangement, she is willing to leave it entirely with us. They may be grouped around a table, two standing and one sitting, or but one standing; or they may be all sitting; let the oldest be in the middle, and the others seated lower on each side, so as to give a good form to the group. It is well to group children with books or toys, as though they were doing something. Nothing is prettier than to put them on the floor among their playthings, with as little formality or order as possible.

"Our next lesson, Focus, I think I will devote to groups."

Correspondence.

PHOTOGRAPHY AND THE INTERNATIONAL EXHIBITION.

DEAR SIR,—The complaints made in to-day's number of the PHOTOGRAPHIC NEWS, respecting the way in which it is alleged that the Committee of Selection for the Photographic Department of the approaching International Exhibition have exer-

cised their functions, are substantiated by such well-known signatures as to render them, at all events, deserving of an impartial hearing. I have formed my own ideas on the subject, but shall leave it to those who are more immediately interested to apportion the blame, should any exist, in the right quarter.

The aim of the present communication is, with your leave, to suggest what I consider to be the most desirable mode of meeting the difficulty, and, at the same time, enabling the general public, as well as the large body of photographers who will, in all probability, be present in London during the continuance of the Exhibition, to judge for themselves how far meritorious works in photography have or have not been recognised by the Committee referred to.

You, sir, will doubtless recollect that last year, under somewhat similar circumstances, a large number of artists, who believed that their productions had been unjustly excluded from the Exhibition of the Royal Academy, resorted to the plan of combining for the purpose of exhibiting them in an adjacent building which they engaged with this view. I would propose that a similar course should be adopted in the case of the rejected photographs, by making them the nucleus, as it were, of a separate photographic exhibition, to be kept open during the approaching season.

Let all photographers who have a care for the advancement of their calling give the project their support; and, bearing in mind the vast influx of visitors from all parts of the world which is likely to take place, there can hardly be a doubt that it will prove sufficiently attractive to warrant its having been carried out. Let admission be free on the presentation of the visitor's card, and let all expenses, such as the rent of suitable rooms, &c., &c., be defrayed by a small fixed subscription payable by those who favour the scheme. It would, of course, be necessary to hold a preliminary meeting, which should be duly advertised, and at which a managing committee should be nominated for the purpose of arranging details, and carrying the project into execution in the most effective manner.

I may mention that, apart from the immediate reason which has induced me to offer this suggestion to the readers of your journal, there is an additional and equally cogent one, to which I desire to draw attention. I allude to the fact that at the Exhibitions of 1851 and 1862, as well as at that in Paris in 1867, the manner in which the displayed photographs were arranged, the very secondary positions assigned to them, and the tendency of the vast collections of more striking objects by which they were environed to eclipse them, as it were, and lure people away, led to their being very frequently overlooked. In short, I could not avoid coming to the conclusion that for the proper display of such a class of objects as photographs these gigantic exhibitions are not the most appropriate arenas.

It only remains for me to add, that having some weeks ago perused a letter in one of the photographic journals hinting at the possibility of certain complications arising in connection with the Committee of Selection already alluded to, I at once determined to forego my intention of sending any of my own photographs to the Exhibition. The present letters from your correspondents satisfy me that my decision was a judicious one, inasmuch as I have been spared the disappointment so naturally felt by them. I may, perhaps, on this account, be the more readily permitted to submit the above proposals for the consideration of photographers generally.—I remain, your most obedient servant,
G. C. WALLICH.

Kensington, March 31st, 1871.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

Str.—The usual crop of complaints in reference to the arrangements of an exhibition may naturally be expected in reference to that which will open in South Kensington next month; but, from the letters which appeared in your last, the crop appears likely to be an early one. In this instance, I must confess, however, as an interested observer, the ground of complaint seems to be a somewhat odd one: it is, in effect, a confession, as well as a complaint. In the first instance, your correspondents grumble that the Committee of Selection have not formed the same estimate of the respective merits of their contributions which they have themselves formed. This was, possibly, a very heinous crime, but it is a very common one. The opinions of artists in regard to their own works often differs from those of persons sitting in judgment upon

them. But, setting this aside, does it not seem, as the artists themselves think that some of their pictures were better than others, that some must have been worse than others? And was it fair to send to an exhibition any but their best?

But the truth appears to be that an unfair motive appears to be suggested; in short, the insinuation which one gathers is, that some members of the Committee excluded pictures which might possibly compete dangerously with their own works. I may be wrong, but I fancy that this idea is plainly suggested. Now, a moment's reflection would show that no such motive could possibly operate. All members of juries are, by the understood rule or etiquette of the situation, well known to be *hors concours*, out of the competition, and as the admission of pictures to this exhibition is, by the published regulations, equivalent to a certificate of merit, it follows that the Committee, being practically in the position of jurors, could not award themselves such certificates of merit, and could not, therefore, exhibit. This being so, it is somewhat hard to undertake a thankless duty which involves self-denial, and meet with abuse as the reward.—Yours,
JUSTITIA.

[We have every reason to believe that none of the Committee intend to exhibit.—Ed.]

MY DEAR SIR,—As I see "Nemo" has made known, in the last issue of the PHOTOGRAPHIC NEWS, that my "Stolen Moments" has been rejected by the Committee, it leaves me only to say it is quite true; at the same time I am very pleased to see that Messrs. Robinson and Cherrill have invited photographers to make known what has been rejected, so that all may be better able to judge whether there has not been a secret motive for the turning out of so many good pictures. I should not have been surprised at having one, or even two, rejected, if they had been the worst of the four I sent, knowing they were limited for space; but to have the best returned, made me think, at first, it was a little spite against me; but as I now perceive it is not me alone, but a general thing, it clearly shows that some other reason existed.—Yours most truly,
1, Oxford Street, W., April 4th, 1871. J. HUBBARD.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Association was held on the evening of Tuesday, the 28th instant, at the Free Public Library and Museum, William Brown Street. In the absence of the President and Vice-Presidents, the Rev. T. B. BANNER was elected to the chair. The minutes of the previous meeting were taken as read, owing to the absence of the Secretary through illness.

Mr. J. A. FORREST exhibited several silver prints with a highly glazed embossed surface, and explained the method of working, which consisted of soaking the print in gelatine, and, while this was in a state of warm solution, pressing the print by means of a "squeegee" into close contact with a sheet of plate glass covered with plain collodion. He stated it was desirable that the collodion should contain rather an excess of pyroxyline.

Mr. TYERMAN asked whether any steps had been taken towards photographing the objects in the Museum, as lately suggested by the Museum Committee.

In the discussion which ensued it was elicited that some of the difficulties in the way were capable of being removed, in which case it was thought that, before long, something might be done.

Mr. EDWIN FLUKES, of Bath, who had kindly promised a lantern exhibition, was delayed on the road; but, upon his arrival, the members were gratified with a succession of architectural views of Wells. They were reduced from the 12 by 10 size at which they were taken for the Science and Art Department of South Kensington, and a considerable number of them consisted of the figures which adorn the west front of the cathedral, the scaffolding now erected for the restoration of which afforded the standpoint whence they were taken. The graceful disposition of the drapery and the elegant early English foliage showed to great advantage, and, at the close of the exhibition,

The Rev. T. B. BANNER proposed, and Mr. HENDERSON seconded, a vote of thanks, which was unanimously awarded, to Mr. Flukes, for his kindness.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF LONDON.—We regret to announce that, owing to the serious illness of Mr. Hughes, his paper on the Carbon Process will not be read on Tuesday evening next. We believe that a paper by Mr. Dunmore, on Large Photographs, will be read.

VICTORIA CARDS.—In the *Photographic Bulletin*, Messrs. Anthony, of New York, having reproduced a recent article from our pages commending the new size of cards to English photographers, takes the writer of the article seriously to task for having stated that the suggestion for a new size first appeared in the September number of the *Philadelphia Photographer*. The offence was a grave one, and we hasten, on behalf of the contributor of the article in question, to correct it. The first published reference to such a size—unless we except Mr. Notman's cards of similar size proposed four years ago—appeared in the *Bulletin* two months earlier than the letter in the *Photographer*. Messrs. Anthony say:—"We desire to correct an inaccuracy in the above article from the PHOTOGRAPHIC NEWS. The first suggestion for the new size of card was not made in the *Philadelphia Photographer*, but was first made, and the name Victoria suggested, in our pages, at the instance of one of our patrons. We desire to say, also, that the first cards of the form ordered or made were made to our order, for us, and were not due to the enterprise of any other person. Further, it may be as well to have it understood that, upon the introduction of the new size, we immediately commenced the manufacture of albums for them." We regret to state that as yet the origin of the new size has not acquired the interest which attaches to the birth of any accomplished fact, and hence our contributor's pardonable error. English photographers are slow to undertake novelties, and we believe that no one has as yet produced Victoria cards. We hope eventually, however, to be able to congratulate Messrs. Anthony on the success of their bantling in this country.

TESTING SILVER SOLUTIONS.—Mr. Napoleon Syrus, writing to confirm the statements of a correspondent in our last as to the great value of Mr. Hart's Volumetric Apparatus, says it has saved him from much trouble and many failures, too often "improperly attributed to the albuminized paper, which is returned, and oft-times another maker tried, and the first entirely discarded, when the real fault lies with the strength of the silver; most of the mealiness, glazed appearance, flatness, &c., resulting from the weak state of the silver, but which, accurately defined, can immediately be rectified."

To Correspondents.

ADVICE TO CORRESPONDENTS.—We are at all times glad to advise our readers on any subject connected with the art upon which information can be given in this column; but to enable us to do so with efficiency, and without unnecessary waste of time and space, it is desirable that a few conditions should be observed by correspondents. All questions should be stated clearly, and written legibly on sheets of note paper, small scraps of paper and sheets of foolscap being equally unsuitable and inconvenient. Where several questions are asked, they should be kept distinct and numbered. Where processes and formulæ have been stated in our pages, it is better for correspondents to refer thereto than to request us to do so, as we cannot, with fairness, occupy space by repeating formulæ which have once appeared, merely to save a little trouble to individuals. Correspondents should use distinctive names or initials: such signatures as "A Subscriber," "An Amateur," and others of a general character being often adopted by a few correspondents in the same week leads to confusion.

A. G.—The lenses of the manufacturer you name have not usually any other marks than those you mention. The firm will, however, verify it for you, we have no doubt, if you make application.

NORTH LIGHT.—The proportions you propose will answer well. We should try blinds, but the alcove background would also be useful. 2. When pyrogallic acid becomes brown from contact with the atmosphere, its developing value is injured; but trial will best determine to what extent. The only remedy is to preserve it carefully from the atmosphere.

F. D.—We used an ebonite bath for some years without perceiving any injurious action on the nitrate of silver solution, and we have not met with or heard of any case in which deterioration of the bath resulted from the use of ebonite. Sulphur is used in the manufacture of ebonite, which is, indeed, a form of vulcanized india-rubber; but we remember when, some years ago, this material was first proposed for use in the manufacture of photographic vessels, we called the attention of the manufacturers to the possible injurious action of sulphur, they assured us that the sulphur was eliminated in the final processes, a mere trace only remaining in any case; and that the surface of the finished vessels was so protected that no possible action could occur. The india-rubber water-tight top must be of pure india-rubber; if vulcanized india-rubber be used, it will act injuriously on the bath.

ANXIOUS.—Almost all the instructions for transferring collodion films which we have given from time to time refer to transfer of the wet film immediately after the production of the picture. For the purpose you require, it is only necessary, after the washing of the picture, to place the plate in a bath of citric acid solution, or water acidified with sulphuric acid, which will cause the film to become loose from the glass; next lay a piece of thin paper, previously dipped in water, upon it, and turn over the edge of the film upon the paper, and then lift the whole away from the glass, and place it upon another glass, which should have previously been treated with dilute albumen or gelatine, and dried. This will effect the end you desire. You will find various articles in our last two volumes, giving detailed instructions, and also in the last two or three YEAR-BOOKS.

R. MORTON DAY.—Such a drying-box as you desire will need to be devised for the purpose, as we are not aware of one already in use. We should have a funnel running through the box, underneath which the gas might be placed, and its heat secured without the fumes entering the box. The drying-box used by Mr. Burgess in the Ebarneum process, described in our volume for 1868, might possibly answer. 2. So far as we can ascertain, there is nothing more efficient for burning-in enamels than a small coke furnace with muffle. Gas can be used, as in Griffin's gas-furnace, but its use is much more costly than coke. 3. The crapy tendency of the india-rubber film may be due to some imperfection in the solution, or to using it too thick. We have used it as you describe without any difficulty, but we used a more dilute solution than that employed in the carbon transfer. It is not a safe basis, however, for transferred negatives, as the india-rubber will eventually perish.

W. P.—The experience you state is a curious one; we have not before met with such a case. It would seem that excess of nitric acid was the cause of the trouble. 2. The lens you mention may be used for groups; but it is not so rapid as a good single lens, which we should recommend for the purpose, if you cannot get the better one to which you refer.

D. W.—We have had no personal experience in the matter. Read the article by M. de Constant in our last YEAR-BOOK, and repeat his experiments, and then determine as to the substitution of pink paper for the blue. 2. Unless the tremor produced by the passing trains is very serious, it probably will not injuriously affect the steadiness of the sitters or plates. We have sat in studios in which we have noticed a perceptible tremor from street traffic, which had no injurious effect on portraits. Have any of our readers experience as to the extent of vibration and its effect produced by an adjacent railway?

ADAM DISTON.—In the absence of any communication from the authorities of the International Exhibition, you may fairly presume that your pictures are accepted. We believe that communication was only made in reference to rejected pictures. 2. The "Smithy" is very good. We shall have something more to say about it. From how many negatives is it produced, where combined, and by what method?

J. S.—The "double salt of iron and ammonia" is commonly known as "ammonia-sulphate of iron," and is sold by all dealers in photographic chemicals, or may be made by combining in their equivalent proportions proto-sulphate of iron and sulphate of ammonia.

JAMES BROWN.—Thanks. In our next.

M. DESUZE.—We have not the address of the gentleman in question. As the PHOTOGRAPHIC NEWS is published a day earlier than usual this week, the office being closed on Good Friday, answers to many Correspondents who would otherwise have received answers this week are necessarily delayed.

Several Correspondents in our next.

A SIMPLE METHOD OF INTENSIFYING.—THE ACTION OF LIGHT ON UNFIXED NEGATIVES.

A FEW years ago, Mons. Blanquart-Evrard published an interesting little pamphlet on the intervention of art in photography, one of the chief aims of which was to indicate a method of strengthening a negative in some parts only. The plan indicated consisted in submitting a developed, but unfixed negative, to the action of light, masked in the parts intended to remain unchanged, and exposed in such parts as required additional intensity. The action of light on the negative in this stage was to continue reduction, and increase intensity.

The fact that light continued reduction of silver in an unfixed negative was not unfamiliar to experienced photographers; but the idea of utilizing this fact appeared to have occurred first to M. Blanquart-Evrard. Oddly enough, after the fact was pointed out, it does not seem to have attracted much attention, nor to have been made available in general practice. We gave details of the process as described by the eminent Frenchman at the time, and verified the method he suggested of utilizing the idea in the local intensification of negatives, but we do not remember to have seen this mode of intensifying used on a single occasion until a few days ago.

During a recent visit to the studio of Mr. Blanchard, whose portraiture, as many of our readers know, approximates more closely to the work of Mous. Adam-Salomon, the prince of portraitists, than that of any other photographer, we enquired details of some of the formulæ and modes of working in use at the moment in producing some very large portraits of rare excellence. Mr. Blanchard has so fully described in our pages and at meetings the processes and formulæ he employs, that we anticipated the reply to the effect that everything was old and well-known, "except," said Mr. Blanchard, "perhaps, the mode of intensifying I am just about to adopt, which is probably less familiar than it ought to be."

The plan in question simply consisted in placing the negative, after development with iron and washing, but before fixing, in direct sunlight for a few minutes, during which time a very definite but delicate change took place. As Mr. Blanchard explained, he very rarely required to intensify his negatives at all, simple development with iron being sufficient; but if any tendency to flatness were noticed in a negative after development, or any want of brilliant points of high light, a few minutes of sunlight afforded the simplest and surest mode of securing the end in question. The process evidently consisted in a further reduction of such traces of free nitrate of silver as remained in the film, that reduction being only effected where the free

silver was already in contact with a reduced portion forming a part of the image, and not at all on the deep shadows where no reduction had already taken place; and further, the reduction was most rapid and complete in the highest lights or densest parts of the negative. Mr. Blanchard added, that where considerable intensification was necessary, few methods of securing it were more satisfactory, simple, and certain than allowing the unfixed negative to remain some time in the sunlight, drying there, and being fixed subsequently.

The question not unfrequently arises in relation to field manipulations, "Is it safe to examine the unfixed negative by open daylight?" We have generally recommended caution in doing this, chiefly because, in the usual scarcity of water, and consequent partial washing, the abundant presence of free nitrate on the plate might cause a risk of general reduction and fog. The experience to which we have just been referring suggests that, after a moderate washing, or after treatment with golden syrup solution, the unfixed negative will not suffer risk when exposed to daylight, as the reducing action of light is induced chiefly in those parts where reduction has already taken place, and that an increase of intensity, greatest in the highest lights, is the result to be anticipated.

SPLITTING OF FILMS.—A NEW CAUSE.

IN the contribution of an "Old Photographer" on another page, a pertinent question is asked in relation to the splitting of films. He suggests that whilst all the varied suggestions as to the quality of the collodion, the kind of varnish, the conditions of keeping, may possibly have some definite relation to the cracking of films, it is quite certain that there is something beyond which remains to be discovered; otherwise, how is it, he asks, that in a batch of negatives taken with the same collodion, varnished with the same varnish, and kept under the same conditions, some will crack, and others remain perfect? That this is often the case photographers know, and, being so, it seems difficult to affirm that the collodion, or the varnish, or the keeping conditions, which prove good in many cases, should be the cause of splitting in other cases. It is clear that some other cause—or, at least, some other predisposing conditions—must come into operation in one case which are absent in the other. Collodion, varnish, and mode of keeping may each tend to produce the fault just when they concur with some other accidental cause, but may be perfectly trustworthy under other conditions.

A letter from a correspondent on another page suggests the possible action of acetic ether formed in an old iron developing solution. But acetic ether, although a solvent of pyroxyline, scarcely, we think, exercises much action on

the film when diluted to an enormous extent by the iron solution; and although some injury might arise, its presence would scarcely account for the irregular occurrence of cracks to which we have just referred, as it is presumable that the same developer would be used with all the negatives of one batch.

But there is another cause in possible operation which may, we think, account for the irregular occurrence of the cracks, and their appearance in one or two negatives of a batch, whilst all the rest enjoy perfect immunity.

When negatives are much forced in development and intensifying, nitric acid is liberated in the precise ratio in which the free nitrate of silver on the film is decomposed, and this might produce a distinct change in the character of the pyroxyline. We have noticed, in samples of collodio-chloride of silver made from collodion in which nitrate of silver had been dissolved and kept some months before the chloride was added, that the film was rotten and contractile, readily splitting up when the plate, coated with the preparation, was placed in the sun to print. Many photographers are familiar with the fact that negatives which have been slightly under-exposed, and have required much forcing in development or intensification, very readily split at times, even in the process of drying. It is not impossible, then, that the one or more negatives of a batch which split, when all the rest of the same batch remain perfectly good, may have been forced in development, and split from two causes: partly because the pyroxyline is acted upon during development by the liberated acid, and partly because, in the process of forcing, the lights are more distinctly piled up than usual, causing an inequality of thickness of film, which must decidedly favour the tendency to splitting.

PROPORTION OF CHLORIDES IN COLLODIO-CHLORIDE OF SILVER.

It has not unfrequently happened that when difficulties and failures in the preparation of collodio-chloride of silver have occurred, we have found, on enquiry, that the cause was a very simple one. The experimentalist has adopted and carefully followed a formula in all points but one; he has made use of some other soluble chloride than that indicated in the formula, substituting chloride of calcium for chloride of strontium, or chloride of magnesium for chloride of lithium, or *vice versa*, without modifying the proportions; and as each of these salts contains a different proportion of chlorine, the element by aid of which chloride of silver is formed, it follows that if the nitrate of silver added to the collodion remain the same, whilst a chloride containing more or less chlorine than is required to combine with it is added, failure, in greater or less degree, must be the result. We have occasionally pointed this out in answer to the enquiries of experimentalists in difficulties. In the *Philadelphia Photographer* we find a compendious and valuable article on the subject, by Mr. Edward Boettcher, the following extracts from which will be found valuable for reference by all working the collodio-chloride process. He says:—

“The great object in making porcelain collodion that will work well is to change all the chlorine from the chlorides of strontium, calcium, or lithium, into chloride of silver by the well-known chemical process of double decomposition. But as the chemical equivalents of the three named metals are widely different, it follows that each requires a different quantity of nitrate of silver to exchange all their chlorine for the nitric acid of the silver. Taking 10 grains of chloride of any of the above metals as a standard quantity, it follows that the lighter the chemical equivalent of the metal, the more chlorine it will contain in proportion to the others; the heavier, the less. From that it follows, that the lighter metals require the most nitrate of silver, the heavier the least.

A calculation from their respective chemical equivalents gives the following result:—

		Nitrate of silver.
10 grains chloride of lithium	requires	67.45 grains
” ” ” ”	magnesium	” 51.16 ”
” ” ” ”	calcium	” 43.05 ”
” ” ” ”	strontium	” 26.63 ”

I would not advise, however, to take just 10 grains of all the chlorides, because with the first two the collodion would print too heavy, with the other two too thin. Taking 6 grains of the chloride of lithium, 8 grains of the magnesium, 10 grains of the calcium, 15 grains of the strontium, and the nitrate of silver in proportion to the above figures, it would give the following receipts for a quantity of 8 grains of collodion:—

		Nitrate of silver.
6 grains chloride of lithium	requires	40.47 grains
8 ” ” ” ”	magnesium	” 43.33 ”
10 ” ” ” ”	calcium	” 43.05 ”
15 ” ” ” ”	strontium	” 39.94 ”

Citric acid the same quantity as the chlorides. No fuming required.

“I, for my part, prefer the magnesium. Collodion made with it after the above formula gives very vigorous clear prints and beautiful tones.”

On one point we do not agree with the writer, as we prefer the presence of a little free nitrate of silver. Whilst commending his hints on the combining value of the chlorides to our readers, we should recommend, as an important element of vigour, the presence of a little excess of nitrate of silver beyond that necessary to combine with the chlorine present.

ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

CAMEO-VIGNETTES—VICTORIA CARD ALBUMS—EDWARDS'S NEW MANIPULATING CAMERA—PHOTOGRAPHY AT THE INTERNATIONAL EXHIBITION—MR. ENGLAND'S OPERATIONS AT ALBERT HALL—TEXTURE OF NEGATIVES AND BROMIDES—FILM SPLITTING—MR. HUGHES AND CARBON PRINTING.

AMONGST the novelties which have been brought under the attention of portraitists from time to time, I think none has been more simple and effective than the cameo medallion or vignette. Its production is easy and cheap, whilst its effect of superiority will readily command advanced prices from the public. In all the recent examples which I have seen as produced in this country, however, there is something missed of the excellence which distinguished the first examples I saw from Milan; the dark border was much deeper than those I have seen issued by English firms. In the Italian prints this border had evidently been printed to a bronze, and in the finished print it was a very deep warm black. Its effect on the half-tones, and the flesh tints especially, was most valuable, giving to a deeply printed face a feeling of great delicacy and tenderness, combined with perfect modelling. Notwithstanding that the style had been noticed in the *News* as a favourite on the Continent twelve months ago, no attempt was made to introduce it into this country until Messrs. Marion, who deserve well of photographers for the enterprise, gave it an impetus by providing apparatus, &c.

Speaking of the impetus which can be given to any novelty by the enterprise of a good house reminds me of the small attention which has been given to the Victoria card, and the want of an album as one of the elements of its success. Will Messrs. Marion and Co. give the new size a lift by providing albums for it?

From what I learn of Mr. B. J. Edwards's new field manipulating camera, it appears likely to supersede everything of the kind which has been attempted before. It seems to afford facilities for working the wet process without either tent or dark room, and without the chance of contact between the silver solution and the developer,

which has been one of the dangerous possibilities of all former contrivances for this kind of work. If the new apparatus effect all it seems to promise, and does not get out of order by constant use, it must prove a great boon to all out-door workers, and will also permit photography to become a drawing room amusement for amateurs.

Notwithstanding the apparently unpromising circumstances, I believe that the forthcoming International Exhibition is likely to prove a good one. The space allotted to photography is small, and is in an undesirably lofty position; but, on the whole, the display will, I believe, be a good one. Some sinister rumours as to the pictures rejected by the Committee of Selection consisting of the best sent in, especially where they were likely to clash in competition with those of one of the gentlemen of the Committee, have been circulating. I am happy to believe that there is no ground whatever for this rumour. The duties of a jury are always thankless, and always offend some one. Those who fortunately win the approbation of the jury are not grateful, as they attribute the decision to their own abounding merit; those who fail to win approbation generally attribute such failure to spite, incapacity, or other sinister motive in the jury. The fact that none of the jury intend to exhibit, whilst it will be a loss to the Exhibition, will worthily tend to silence envious tongues.

Speaking of the Exhibition reminds me that Mr. England has undertaken the production of photographs of the Exhibition in the Albert Hall. Oddly enough, the original concession for photography in connection with the Exhibition was obtained by Messrs. Johnson, of Castle Street, Holborn, whose name is well known in connection with the catalogues of former exhibitions. They made arrangements with Mr. Nottage, of the Stereoscopic Company, and he with Mr. England, so that it eventually reaches the hands most capable and experienced in such work. At the opening of the Albert Hall, his arrangements had been made for securing a group including her Majesty and other distinguished persons whilst engaged in the opening; but, at the last moment, some officious official of South Kensington, in temporary power, refused to permit the camera to occupy the necessary cognate of vantage, and nothing was obtained.

In some interesting remarks which recently appeared in your pages on the colour and texture of negatives, Mr. Lea has some comments on the printing qualities of creamy negatives. He mentions the well-known fact that creamy negatives yield rich, silky, velvety-looking prints. He remarks that such negatives are generally free from granular deposit, and that the use of a large proportion of bromides in the collodion is, amongst other things, an important cause of coarseness and granular crystalline deposit in the negative. Of course Mr. Lea has, under some circumstances, found—or believed that he had reason to conclude—that this was the case. But I cannot but believe that, as a general fact, the notion is erroneous. That a creamy negative gives good, rich prints almost every photographer well knows; and that such negatives are free from granulation and coarseness of texture, being more actinically opaque than visually opaque, may be easily determined by examination. But I do not think that the presence or absence of bromides in the collodion has much to do with the creaminess or granularity. With the same collodion it is not difficult to produce creaminess or granularity at will. Indeed, in the course of experiment, I have done so; and I have experimented with almost every proportion of bromide without producing granularity by its excess. The primary condition of producing a creamy negative, other things being equal, is full exposure. The primary cause of greyiness, granularity, and poverty in a negative is under-exposure. With a bath in good order, moderately new, neutral, or nearly so; a good collodion, with plenty of bromide; a bright light, full exposure, and nearly freshly mixed iron developer, a negative with the creamy quality and fine bloom which generally indicate perfection in the gradation and good printing cha-

racter, may always be obtained. With an old bath, containing much acid—or, worse, acetic ether—a collodion with little or much bromide, or none, short exposure, and old iron developer, a grey, thin, hard, patchy, granular negative, worthless for printing purposes, may, with equal certainty, be secured. The use of old discoloured collodion, the ether in which has become ozonized, is a cause of grey, granular negatives. The use of a weak old developer, acting slowly, and rendering much forcing necessary to bring out detail, is a sure source of granularity in the negative; and the grey, granular negative, as Mr. Lea observes, is very deceiving to the eye. It often seems to possess good gradation and sufficient intensity, but prints wretchedly.

The film-splitting difficulty has been again discussed, but not, I fear, settled. Many of the causes have doubtless been indicated, but one puzzling circumstance remains: how is it that, in a batch of negatives taken the same time, with the same collodion and chemicals, varnished with the same varnish, and kept in the same conditions, that one or more films will split, whilst all the rest remain perfect? This little fact—and most photographers are familiar with it as a fact—seems to upset all theories as to the cause of splitting being found in the quality of the collodion, the quality of the varnish, or the conditions of keeping. I commend the consideration of this fact to those who are engaged in investigating this important subject.

The absence, at the next meeting of the Photographic Society, of Mr. Hughes's paper describing his experiences in carbon printing, will cause much disappointment; and the regret will not be lessened when it is known that the serious illness of Mr. Hughes, confining him to his bed, is the cause. I learn that he is happily improving, and that the paper is only delayed, not lost. I have seen some of the carbon prints he has been producing, which could not be distinguished from silver prints on albumenized paper in texture and colour, even by experts. As this is the point of excellence to which photographers desire to attain, this will doubtless satisfy them. Meanwhile, the more cultivated in art matters ask, Is an albumenized print the highest standard of monochrome in colour and texture? Luckily, as such questions will arise, carbon printing can meet any exigency of this kind which taste may demand.

THE PURPOSE AND LIMITS OF RETOUCHING.

BY W. HARTMANN.*

WHILST striving to improve the purely technical operations of the camera, the desire arose among photographers to know more of the art of retouching, and thus, by means of the pencil and brush, to impart to the photograph those minor beauties which the painter—without, perhaps, being cognizant of the act—adds to his production, according to his skill and good taste. How far it is possible for the photographer to act as painter, and to improve his work by additions or modifications; how far he dare embellish his portrait without interfering with its semblance to the original; and how far, in fact, the limits of retouching may be carried, will form the subject of this communication. The ideal of beauty flutters before all of us, and an experienced eye is necessary to separate what is material and what is of no consequence in a portrait, and to distinguish between effects of an effective and injurious character. The perfection of the technical part of the work, and the limit or extent of the retouching, must depend upon the capacity of the artist.

In regarding any human face, it is at once apparent that the prominences formed by the facial bones which stand out so clearly are the least susceptible of modification. The surface of the forehead, the nose, jaws, eye-prominences, always bear some proportion to one another. It is these parts, together with the position of the eyes and mouth,

* *Photographische Mittheilungen.*

and shape of the nose, which constitute the striking characteristics or likeness of the portrait. More or less contraction of the muscles, especially of those at the corners of the mouth and eyes, and those of the cheeks and cheekbones, give the expression to the countenance. These features must, therefore, be handled by the retoucher with the greatest care. The skin, on the other hand, as likewise the hair, dimples, or relaxed and loose surfaces, may be treated with more freedom. At the same time, it must not be forgotten that the skin, owing to its tint and blemishes, is often more strikingly reproduced than slight dimples, which are rendered only by very light shadows. To render the face more plastic by remedying these defects is the principal aim and principal difficulty in the art of retouching. We will now consider these main points separately, and study the different features, their change in age, their difference in the sexes, and their value as regards expression and likeness.

The forehead, in children very round and soft, becomes exceedingly marked in the man, and separated into several flat surfaces, being one of the principal characteristics of his face. The upper part of the forehead is that portion of the human head which shows most plainly the form of the skull, and only the lower part is covered with the wrinkles which lie just above the eyes. When lighted up, the surfaces of the forehead are very distinctly marked, and here the skill of the retoucher is necessary to sober down the boundary lines so that the forehead may appear as much as possible like one surface. A too much rounded forehead—which is, with women, passable—renders a man weak and unhandsome, and, for this reason, a flat surface should be secured. The skin-folds in the forehead are disposed upon the lower portion according to the tightness of the skin, and run parallel with the prominences above the eyes. As they are often seen in middle age, and follow quietly the shape of the forehead, they may generally be allowed to remain in a softened form. The perpendicular creases or wrinkles which occur in later life, and which run across the former and interfere much with the beauty of the forehead, may be touched out altogether. At the most, it is well to allow the two principal of these wrinkles, which come from the root of the nose, and, to some extent, annul the horizontal lines, to remain upon the portrait.

The patches of hair on the temples, so soft and delicate, are always turned to good account by painters. The eyebrows, while differing much in density, form, and colour, are always of æsthetic value, from the fact that they follow the arch of the eye-hollows, and form the boundaries of these. For this reason it is well to soften down any hairs that may be growing out of place, and to define clearly the arches of the brows. A meeting of the eyebrows over the nose is considered a defect; it lends to the face a gloomy expression, more especially as a shadow is already cast upon this portion of the countenance.

The sum of a retoucher's labours are, therefore, confined briefly to rendering prominent the plane surfaces, the considerate treatment of hard and soft hair-patches, the toning down or removal of upright and unimportant creases in the skin, the softening of the large cross-wrinkles, and rendering the arched eyebrows more clearly defined. To what degree these operations may be pushed must, of course, be regulated by the age and sex of the sitter.

The head seen in profile often appears not to project far enough back. Smallness of the head in the presence of a large face imparts the characteristics of an animal. A little may, therefore, be added by retouching; at any rate, the head will then appear more important. In the same way any unsymmetrical arrangement of the coiffeur may be remedied by judicious additions or removals. Blonde hair which prints too deeply may be bettered by employing a body colour, and half-shadows in black hair which have been somewhat under-exposed may be harmoniously put in by means of a lead pencil. The same also holds good with whiskers and beards.

In the treatment of the nose the same holds good that was remarked of the forehead, for a muscle extends from down the length of this feature, rendering its upper surface more or less flat. The whole length, therefore, should be rendered clear, and, if necessary, a high light introduced to make the feature stand out in relief. The shadows at the side of the nose must be covered, and may be lessened should the feature appear too broad. Crooked noses may often be remedied. The shadows of the nostrils should not remain perfectly black. Attention should be paid to the fact that the shadow upon the lower part of the face be not of the same depth as that cast by the nose. The lighting up of the point of the nose is then more marked, and the effect more plastic. As regards the profile view of the nose, the outline of the same given by the bridge, generally so characteristic, must never be altered; at the same time, the fleshy portions, which, in old age, often increases to a marked degree, may be somewhat lessened without injuring the likeness.

The mouth, from its facile motion, by the lowering or elevating of its corners, and by its greater or less breadth, is the best criterion of the sitter's disposition at the time being; in many cases—as in the instance of children's portraits, where a happy expression has not been secured—much may be done subsequently by a clever retoucher to remedy the defect. In the first place, the lips should be separated from the line of their meeting, as also the corners of the mouth. The lips should, moreover, be cleared from any ugly creases or fissures in the skin. The form of the mouth may easily be improved by rendering its limits more prominent, and its shape more uniform. When, as sometimes occurs in old age, the angles of the mouth droop, and are continued by wrinkles in the same direction, care must be taken to soften these markings down, and to prevent them from appearing like a continuation of the mouth. Above the mouth are also seen in elderly persons very marked depressions and wrinkles, which appear often like an unshaven beard; these may be removed. Attention must, moreover, be paid to the various high lights between the nose and the mouth, and especially to that one stretching from the division of the nostrils to the prominence in the middle of the upper lip. The sharpness of the outlines of the lips is very changeable. Soft and prominent lips are more lighted up than those of a rounder nature, and, in the former case, their limits should not be rendered too prominent. The corners or angles of the mouth may be softened down, and in elderly persons reduced, but must never be wholly removed; and this modification may be carried to a greater extent below than above, as the sinking of the lines of the mouth is a sign of depression or sadness. In most instances the teeth come out very dark; the filling up of the intervals so as to fuse them into the lips is to be recommended when an open mouth is undesirable, and when the opening is not so large as to add materially to the thickness of the lips.

The eye is one of the most important parts of the face, and for this reason it is important for the photographer during the exposure to look well to its expression and direction. Nevertheless, there is generally much that may be done by the retoucher in improving the feature, and some instances in which the brush may be used with advantage may be here mentioned. The clear and bright expression at the commencement of the exposure oftentimes becomes dull, the eye-lids and pupils sinking almost imperceptibly, and the high lights either becoming blurred or obscured by the lashes. In this case the best remedy is to define sharply the outline of the iris, and to cover the high lights. It also frequently happens that the high lights are brighter in the eye that is in the shadow than in that upon which the light falls, and, in this instance, it is, of course, necessary that both points of illumination should be equalised. In the same manner the lower lids are often rendered unsharp by continual winking. At their edge is generally seen a sharply defined and very bright light, which is almost

always of a brighter tone than the whites of the eyes, and this may easily be improved upon the negative. In the white of the eye, especially in aged sitters, are to be remarked very prominent little veins, which impart an unpleasant spotty appearance to this feature in the photograph. These may be removed altogether by the retoucher, only care must be taken that the white is not too bright.

As regards the neighbourhood of the eye, the fleshy portion situated directly over it strikes one generally as being disagreeably dark. This, as also the form of the eyebrows and the folds of the upper eyelid, may be touched and lightened, so as to assimilate more to the original. The so-called lacrymal bags below the eyes are also portions of the face which are reproduced of too dark a colour. The folds or wrinkles in the last-named which are generally to be seen may be allowed to remain, although any cross wrinkles should be removed, so that the folds may be cleared and run parallel to the outlines of the eyes to meet at the angles thereof. Immediately next the lowest fold under the eye comes the cheek, of firm fleshy consistence, which it should be sought to reproduce in a rounded form by a gathering up of the lights. A shadow running down between the cheek-bone and the inside corner of the eye is either due to the colour of the cheeks, or to a thinness of the face, and this lends to the countenance a saddened, care-worn expression. When but slight evidence of it is apparent, it may be altogether removed, and in any case it must be softened down. As regards the wrinkles at the outer corners of the eyes, or so-called crow's-feet, these are much too characteristic to be removed altogether.

The outline and surfaces of the cheeks are determined by the position and degree of prominence of the cheek-bones. From some points of view the latter are sometimes reproduced too distinctly, and when this is the case some improvement may be effected by subduing the same. In reference to the surface of the cheeks, care should be exercised that the front and sides thereof are divided by distinct yet softened lines, so that the shadows created by sunkenness of the cheeks may be toned down as much as possible. A dark tint arising from the bronzing of the cheeks, as in the case of military men, farmers, and those much exposed to the action of the sun, may generally be reduced by covering upon the back of the negative.

The chin possesses generally a fat dimple, especially with elderly people and good livers, and this, stretching below, covers up a large portion of the neck in an unbecoming manner, and, imparting a broad effect to the lower half of the face, interferes with the proportionate beauty of the head. As already remarked, fleshy parts of this nature belong to those portions of the face which allow of retouching to the greatest degree. In cases of profile, considerable pruning may be effected, and in a front view, by removing the lower folds of skin, a portion of the double chin may be added to the neck. Careful manipulation is, however, necessary in correcting the outline and the more prominent part of the chin; the little hollow in the middle of the chin must be subdued, as it often appears as a crevice or darkened cavity.

The neck may be treated in the same way as the chin. When the neck is thin it is well to soften down the veins, sinews, and the like, as also the shadows caused by the same, and by suitable additions or removals to render it of normal dimensions. The same may be said of the shoulders, the bosom, the arms, waist, and hands. In these matters one can, of course, go to work in a much more confident manner, seeing that individual resemblance is by no means so important as the facial features. Angular and thin shoulders, spare arms, indifferently hustled, and all matters which interfere with the beauty of women, the painter avoids under all circumstances; and the photographer should proceed in the same manner as soon as his technical knowledge, skill, and taste, allow him to do so. Improvements are very necessary indeed in correcting the outline of the hair, and the folds of drapery in ill-fitting costumes.

By means of the retouching brush it is possible to add very much to the value of negatives, and especially to those in which a large number of defects may be removed, for it is not always possible, even at the cost of considerable trouble, to obtain a perfect portrait at the time of sitting.

The above are the main principles upon which the art of retouching, when not carried out superficially, is based. I am convinced that any artist employing these rules in a conscientious and careful manner, whilst working at the difficult task of retouching, will be successful in producing fleshy and life-like pictures; whilst an indifficient covering up and equalising of all shadows produces that description of plaster-like bloated portraits which is quite opposed to any anatomical modulation, and to the ruddy appearance of the human skin in health. By sketching from nature, and assiduously studying the character of good portraits, of new as well also as old masters, and by making collections of worthy copies, much improvement will be experienced, both in taste and judgment, and I can be scarcely wrong in pointing out this way as one certain to lead to the desired goal.

THE AUTOTYPE PROCESS.

BY TOM TAYLOR.*

THE reproduction by photography of the colouring of nature was once called a *desideratum*. It may now, with more propriety, probably, be called a dream. The nearest approach, judging by our present lights, that we are likely to make to this result is that obtained by the Autotype process, to which I propose to devote the present article.

It gives us, at least, monochromatic colour, enables us to reproduce a facsimile in colour—as in lines and light and shade—of any drawing in which one pigment only has been used, be it red or black chalk, sepia, indian ink, bistre, common ink—in short, any colouring matter or tint that can be incorporated with gelatine. Now though this is very far from a realization of their aim who have toiled at the imitation of natural colours by photography, it is a result of immense importance for the reproduction of drawings, in which the colour is of great artistic importance, and materially influences both style and treatment. It is only when we have examined the magnificent series of such facsimiles, including all that is most precious in the priceless public collections of drawings at Florence, Venice, Milan, Vienna, Bale, and Paris, reproduced by the indefatigable enterprise of Adolphe Braun at Dornach, that we can appreciate the vast importance of the Autotype process to the future of fine art education, and the honours it has already bestowed on lovers of such art in a branch of it hitherto practically out of the reach of all but millionnaires.

This is but one field of the Autotype. It has open to it another as wide, and not less fruitful, in the reproduction of drawings of the time, pictures, rare engravings, and prints from ordinary negatives.

Besides its power of reproducing monochromatic colour, the Autotype process has another immense advantage over ordinary photographic processes. As far as we can form a judgment, its productions are, humanly speaking, as permanent as the pigments employed in them; and many of those most used in drawing—as lamp-black, red or black chalk, and indian ink—are among the most permanent known to art. There is no reason, according to the most competent chemical judgments, to think Autotypes more perishable than engravings. The printer's ink determines, in fact, the life of both.

Having set forth the two great distinctive features of the Autotype, let us here say so much of the process as is necessary to understand how these long-sought advantages of colour—monochromatic, at least—and durability have been obtained. We have not room here to review the many gradual steps by which, like almost all inventions, this at-

* *The Portfolio*.

tained its present position. They are carefully detailed in the Manual published by the Autotype Company.

The basis of the process is the action of light on bichromate of potash in contact with organic matter. Coat a paper with a mixture of this bichromate and gelatine; expose it to the light, under a photographic negative, in a common photographic printing-frame. Where the light reaches the coated paper freely—*i.e.*, in the high lights of the negative, which are the extreme darks of the picture to be printed—the bichromatized gelatine becomes insoluble. Where the light is entirely shut out from the coated paper—*i.e.*, in the deepest darks of the negative, which are the brightest lights of the picture to be printed—the bichromatized gelatine remains perfectly soluble, and may be entirely washed away. In the half-tones—to be reversed, be it remembered, for negative and picture, by reading half light in negative for half dark in picture, and *vice versa*—insolubility is attained, or solubility preserved, in proportion to the degree in which light is shut out from or let in to the coating of bichromatized gelatine.

Now mix a pigment with your gelatine, and your lights, darks, and half-tones, are at once translated into gradations of that pigment, be it red or black chalk, sepia, indian ink, common ink, bistre, or what you will.

The practical difficulty in this process was to preserve the half-tones of the printed picture till they could be fixed on some durable support. They were floated away in the washing process necessary to get rid of the soluble parts of the print—its lights. It was Mr. Joseph Swan, an inventive chemist of Newcastle-upon-Tyne, who so far overcame this difficulty as to make the process commercially workable; but it was rendered practically and generally available by the patents of Mr. J. R. Johnson, the Chemical Director of the Autotype Company. Mr. Johnson has devised a new and highly improved pigment paper; has discovered that when an Autotype print is impressed on this paper it may be attached to a permanent backing, or support, without any cement. If this backing (a plate of zinc, glass, porcelain, &c.) be coated with a fatty substance (infusible at the temperature of the water used for washing away the soluble coating, but fusible at a somewhat higher point), the picture film may be readily detached from the backing. All that is necessary is, that it should be mounted on properly prepared paper by any of the many colloids* that may be used for the purpose.

The Autotype process of printing, preparing, and mounting an impression, though it take some time to describe, is, in practice, both easy and simple. The best way to understand it is to go to 36, Rathbone Place, on a Friday, on which day, Phœbus permitting, the process is shown to all comers. Here the student may follow the production of an Autotype, from the insertion of the pigment paper in the printing frame till the dry print on its enamelled paper is detached from the "permanent backing," or plate, which has given its cohesion while the soluble portions of coloured gelatine were being washed away. We have said that the process is permanent, humanly speaking. This is strictly true. In the ordinary photographs produced by aid of silver and toned by agency of gold, wash the chemicals out with what care we may, it is practically impossible to secure such a thorough purification as will ensure the print against first turning yellow and then gradually fading, under the sulphurous influences of our carbon-impregnated atmosphere. In the Autotype process, if the pigment be inert—*i.e.*, chemically harmless—the gelatine that is mixed with it may be relied on. It is not soluble gelatine, liable to change from damp, but gelatine made insoluble by its combination with an earthy basis. Dr. Markham has aptly compared the Autotypic medium of reproduction to transparent leather or vellum, known, by the illuminated manuscripts which have come down to us, to be, of all organic bodies, one of the most permanent as a basis for colours.

* Gums or glues,—means of stickiness, in fact.

When the process is complete, an Autotype print shows us nothing but the insoluble gelatine imbued with gradations of pigment, from darks through half-tones to highest lights, held together by a paper backing.

It is impossible, as far as the writer can judge, to exaggerate the perfection of the reproductions by this process of the drawings of the great old masters. It is as impossible in this paper even to indicate the specially interesting examples, among the many thousands of such reproductions brought out at very reasonable prices, from half-a-crown upwards, both abroad and at home. Suffice it to say, that there is no reason why every lover of such things should not have his portfolio of great thoughts of great masters, practically not to be distinguished from the originals. More important still, there is no reason why, instead of the rapid, smoothly-hatched French lithographs of Jullien and Co., our schools of art should not be furnished, by means of Autotypes, with selected examples of the best drawings of the greatest artists the world has yet known: such giants as Michael Angelo and Raphael, and all the great Florentines before and after the Renaissance; Titian and the Venetians; Leonardo and the Lombard masters; Dürer and Holbein; the Carracci and their Bolognese pupils; Rubens, Vandyke, and Rembrandt; to say nothing of the smaller Dutch and Flemish masters. We cannot imagine any better corrective of the faults which have been, with good reason, alleged against our present art-school system, than the study of such examples as are thus brought within the student's reach. They will teach him the meaning of real exactness and expression as distinguished from superficial smoothness, and laborious neatness of manipulation; while for the higher lesson, how life and meaning are to be conveyed, what intense and protracted pains must be used to reach the ease of perfect truth and nature, a good selection of such drawings would be simply invaluable.

We are glad to find that the Autotype Company recognise the importance of this employment of the invention. They are adopting means to cheapen the multiplication of school copies of the figure, in the shape of facsimiles of hands, feet, limbs, and torsos from the drawings of the old masters, by a patented process of mechanical printing, one of the many modifications of the method invented by Poitevin, in which a film of gelatine, photographically acted upon, is made to do duty as an engraved plate, from which impressions are taken in the printing or lithographer's press. As far as we have seen, all methods of mechanical or sun-printing have one common shortcoming—want of perfect delicacy and continuity of gradation, and a peculiar granulation, or meanness of texture, particularly in the shadows. Still, this method is well adapted for works requiring cheap and rapid multiplication, such as is needed in the case of copies for school use, to which the Autotype Company propose to apply it.

(To be continued.)

COFFEE AND OTHER DRY-PLATE PROCESSES, WITH PRACTICAL DETAILS OF A NEW DEVELOPER GIVING EASE AND CERTAINTY.

BY A. DE CONSTANT.*

§ IX.—THE FIXING OF THE IMAGE.

In the face of the many accidents which yearly happen with cyanide of potassium, it is really inexplicable why the same is still used in our studios, seeing that it is easily replaceable; and surely one is compelled to breathe quite sufficient of unhealthy fumes and vapours in photographic operations, without needlessly having recourse to a further danger. For this reason, I have determined to banish cyanide of potassium from my studio. A bath of saturated hyposulphite solution is employed instead. But I find that for dry plates it is very necessary to prolong the operation of fixing, for the negatives are very loath to part with the

* Continued from p. 162.

iodide of silver contained in the film. And often one finds, upon printing, that there still remains trace of that compound, large patches being produced, which, on exposure to the sun, become more and more intense. At the same time, when it is carefully ascertained that the iodide has been completely removed from the margin of the plate, one may rest assured that it no longer exists elsewhere, and that the image has been well fixed.

§ X.—VARNISHING AND PRINTING.

Generally speaking, dry plates soon lose their moisture; but it is, nevertheless, necessary to make sure that they are perfectly dry before applying the varnish, inasmuch as the least trace of dampness gives rise to irreparable stains and defects. It is, moreover, important to employ a varnish of good quality; for if the same softens by the action of the sun, the *cliches* are rapidly injured. Yellow shellac dissolved to saturation in good ordinary alcohol yields a varnish exceedingly impervious to the sun, for it hardens very quickly. But the film of such a varnish will not admit of retouching, and for this reason it is necessary to mix a little gum benzoin, to render it somewhat softer. Negatives varnished with this compound must, however, be allowed to remain a dozen hours before they are in a condition to be printed.

For landscape pictures retouching is not resorted to as in the case of portrait photographs, but, nevertheless, I think the process might be applied with advantage, either upon the image itself, or upon a coating of varnish placed at the back of the negative. The brilliant surface of the varnish is removed, where the retouching-brush or pencil is to be applied, by rubbing on a little pounce powder gently with the finger. Upon the matt surface thus produced it is possible to work easily, the detail of the picture being readily improved by the use of a drawing stamp covered with red chalk. In this latter case, the retouching is conducted on the same side as the image, excepting where large surfaces have to be worked upon, when it is better to operate on the back of the negative, so as not to destroy the delicate half-tints, which may not be without effect in printing. By means of an ordinary pencil one is capable of perfecting or correcting any details in the trees and foliage. All this, if done with a little skill and discretion, will improve the plate wonderfully.

I have already said, that according to the preservative employed, the *cliche* assumes a different colour when developed with pyrogallic acid. With the coffee-gum process the tint assumed is that of a brownish red, which possesses in general sufficient density to yield vigorous impressions. Brilliant *cliches*, which have a transparency so high that one may readily distinguish objects placed behind them, may be very taking at first sight, but are, nevertheless, unsuitable for printing; coffee, for instance, when used by itself, yields a film of this nature. The second development with iron solution which I propose is for the purpose of doing away with this transparency, by giving body to the image in the half-tones.

As it is impossible, however, always to obtain *cliches* of an absolutely perfect nature, it is well to know of means by which less satisfactory plates may be taken full advantage of. For this reason, I mention a few manipulations besides that of retouching, which may be useful. If the *cliche* is too hard and transparent, the defect may be remedied by placing at the bottom of the printing frame a sheet of ground glass somewhat larger than the plate, which rests upon the matt surface; or, instead of ground glass, a piece of matt transparent paper may be used. If the whole of the foreground has remained positive, the transparent paper may be cut so as to form a graduated mask, which is pasted over the most transparent part of the negative; and this paper may, moreover, be touched up by means of a stump and some red chalk. But where the *cliche* has been solarized, or is too weak altogether, it is exceedingly difficult to improve, and, indeed, the best mode of proceeding

is then to employ an energetic and highly albumenized paper in the frame, placing the same in the shade to be printed.

As a rule, when printing is conducted in the shade, the results are superior to those produced in the sun; but as, in such case, special arrangements require to be made, and more time is necessary, it is not always convenient to proceed in this manner. When, therefore, printing in the shade cannot be undertaken, it is best to cover the frames with a sheet of ground glass, the matt surface uppermost; and, indeed, this precaution is indispenable when the *cliche* has been retouched or masked, as any traces of tampering with the same are thus rendered invisible.

§ XI.—THE TONING OF PRINTS.

In treating of the operation of toning, I know very well that I transgress the limits of my subject; but, knowing the many formulæ from which the *debutant* has to choose, I cannot hold back a word of advice, and would recommend him to adopt a gold solution, which is especially suitable for amateurs, and will save much cost and trouble. For, after having experimented with upwards of fifty processes, I have at last joyfully returned to the simple and reliable toning solution suggested by that skilful chemist, M. Davanne, which is, indeed, nothing further than a neutral gold bath. The manner of compounding it is as follows:—

Water	1,000 grammes
Double chloride of gold and potassium	1 gramme
Powdered chalk	5 to 10 grammes

The mixture is prepared some eight hours before employment, and will remain good for almost any length of time if care is taken to bring it up to its original strength by the addition of more gold every time it is used.

To do this properly, one should have a bottle containing two grammes of chloride of gold and potassium dissolved in one thousand grammes of water; and of this liquid two and a-half cubic centimetres are added to the bath for every quarter sheet of albumenized paper toned. The toning solution is thus always ready for use of uniform strength, and kept neutralized by the chalk, which is allowed to remain at the bottom of the liquid, and of which a pinch is added from time to time.

M. Davanne, no doubt, has recommended the double chloride of gold and potassium from the fact that he believes the gold to be purer in this form; but I have found ordinary chloride of gold of good quality to answer the purpose satisfactorily. In any case, however, this toning solution will be found very efficient, and capable of furnishing any tone that may be desired.

Here my task terminates. I shall be happy if the dry process of which I have here given the details should meet with favour; and I trust, moreover, that the sentiments I have expressed upon the subject will not be too severely criticised, seeing that my only wish has been to render myself useful to my colleagues in communicating, in perfect frankness, such experiences as I have acquired from a long and diligent study of the subject.

CHILDREN IN THE STUDIO.

BY ISAAC WILFE.*

Or all the subjects which try the patience of a photographer—and their number is legion—there is none like children for firing the temper, and wasting the time and chemicals of the artist of the sun. I am fond of children; I may say I love them, I mean in the studio when I have no better subjects; but if I have children of large growth, I love to have the little ones at home. But as long as there are photographers and children, so long will there be subjects of the kind I am going to describe.

There is a stout lady about forty-five years of age, who

* Read before the Oldham Photographic Society.

has come along with her married daughter, about twenty-four years. This daughter has got a son about one year and six months old. This son is called Philip Henry, and, being a fine little fellow, they have brought him for me to take a portrait of him, and they tell me if I can make a good one of him they will come themselves, and have a dozen cartes-de-visite taken to send to America, and to give their friends, and I must be sure to make them good, because they have to go a long way. How would you like the baby taken?" is my enquiry. "Oh! he must stand, to be sure." "But he would be better taken on your knee," I reply. "But he is too big to sit on my knee," the mother says.

I see it is of no use trying to persuade the fond mother that her child may not be still. She tells me I have no need to fear him, that he could stand still; and how forward he is, and other good qualities, all of which, of course, I understood at once. The child is dressed in a light red or magenta-coloured frock, the eyes are blue, the hair is light, and curled on the top of his head as if they wanted to make a show of him. They have brought a small wooden horse and a whip. He is to be whipping his horse while I am taking his portrait. Of course, I tell them it is of no use attempting to photograph him whilst he is moving his hand. I prepare a plate, and put his head in the rest. I hasten to the camera to take off the cap, when, of course, he moves. It is failure No. 1.

To pacify him, he has an orange bought. He makes an incision in it. I ask them to take the orange from him, when he cries loudly. Then he must have toffy and humbugs. Meanwhile, the photographer thinks they are all three humbugs. Philip Henry being an only child, I am reminded of the Spanish proverb, which says, where there is an only child, there are three fools in one house. I am ready again with plate No. 2. They wipe away his tears. All is ready now, except his lips are a little apart. I ask him to please to close his mouth. He then opens it wide. Mother and grandmother both laugh. I then ask him to open his mouth. He now closes it.

I begin to focus again, and coax or threaten him to get him still; I tell him to look for a bird coming out of the hole, and that if it comes out he shall have it to take home. He is now quiet. I take off the cap; but this time he lifts his hand to his mouth, when lo! he has three arms. I tell the fond mother he has moved again. While I am preparing plate No. 3, they say, "You should take him now; look how still he is! Just now you should be ready, while he is still." The mother forgets he should be still when I am ready.

Losing one hour in time, and nearly all my patience, I persuade them he can be taken better on the knee. Mother says that grandmother must sit with him; I recommend the child's mother; but it is ruled otherwise. The mother is not dressed for her portrait, so grandmother takes her seat. She being an artist herself, it makes me rather jealous of her. Pardon me for calling her an artist, for she is one, nevertheless, for she is the mistress of the Red Lion Inn; and are not all the publicans painters, though it takes them twenty years, sometimes thirty years, to produce a correct likeness of one of their customers?

For a description of the old lady's figure, I refer you to a portrait she has brought with her, taken by that clever artist, Mr. Brown, of Regent Street, London, when on a visit to the Great Exhibition. The portrait is handed to me for inspection, and I find it a good one of the subject before me. The fact is, the old lady is sitting on a tall chair, and, being very stout, it would puzzle an ordinary person to tell whether she was standing or sitting. She calls Mr. Brown's attempt of her portrait a brute of a thing; she never had a good one out of all the number she had had taken; she hoped I would make a good one of her and the child.

The child is of fair complexion, light blue eyes, of a lively disposition, a frock that takes a dirty white. The old lady is very stout, of ruddy countenance—I fancy

takes tea in her rum—light blue eyes, sandy hair, her bosom nearly touching her chin, and when she breathes her bosom swells up and down like waves on the sea on a calm summer's night.

I remember, when young, a motto which says, that nothing is impossible to a willing mind. Now, I am willing to try all the powers of patience and perseverance which I possess, but I think it impossible to make grace, roundness of face, and a model of perfection out of the subjects before me.

The old lady takes her seat, and the child is placed in her lap, and just perched on the front of her knee. I want to take it as quick as possible, and put in the largest stop I use. I tell her to press the child to her bosom; to hold his head firm. I succeed, after shouting, whistling, and other noises, in getting what I consider a good result; but grandmother having a red face, and I wishing to make it clear, the child's face is one patch, which will not do at all. They tell me that they do not care about grandmother's portrait; it is Philip Henry's likeness they want. I tell them I can make a good portrait of the child, but grandmother will be a little dark. I make another attempt; and behold! it is crowned with success. The child is a model of beauty, but grandmother is dark. Both mother and daughter laud the portrait of Philip Henry, but grandmother is a little too dark. They wish me to try once more. It is no use me telling them that either one or the other will be spoiled; that it is impossible to make both alike when it takes six seconds for grandmother and only two seconds for the child. "Just try once more, Mr. Allprofit—do; and then we can choose out of the last three negatives which we shall have."

I want to get rid of such subjects, so I summon courage to try again, and manage to get one where neither is good, but both are moderate; then they give me the large order of three cartes-de-visite, which, at my price, is three shillings!

WEIGHTS AND MEASURES IN CONTINENTAL FORMULÆ.

THE French or metrical system of weights and measures is adopted almost universally in continental Europe; and, as our readers frequently meet with formulæ stated in terms of the metrical system, the following information will be often found useful:—

The unit of French liquid measures is a cubic centimetre. A cubic centimetre of water measures nearly 17 minims (16·896); it weighs 15·4 grains or 1 gramme. A cubic inch of water weighs 252·5 grains.

1	cubic centimetre	=	17 minims nearly
3½	"	=	1 drachm
23·4	"	=	1 ounce
50	"	=	1 ounce, 6 drachms, 5 minims
100	"	=	3 ounces, 4 drachms, 9 minims
1000	"	}	= 35 ounces, 1 drachm, 36 minims
or 1 litre,			
= to 61 cubic in.			

The unit of French weights is the gramme = to 15·4 grains; thus a drachm (60 grains) is nearly 4 grammes (3·83). An easy way to convert grammes into English weight is to divide the sum by 4, which gives the equivalent in drachms very nearly thus:—

Grammes.	Drachms.	Oz.	Drchm.	Grains.
100	+	4	=	25 = 3 . 1 . + 43

TABLE TO CONVERT GRAMMES INTO GRAINS.

Grammets.	Grains.	Deci-grammes.	Grains.	Centi-grammes.	Grains.	Milli-grammes.	Grains.
1	15·4346	1	1·5434	1	·1543	1	·0154

The unit of French measures of length is the millimetre.

The millimetre	measures	00.0393	inches.
The centimetre	"	00.3937	"
The decimetre	"	3.9370	"
The metre	"	39.3707	" = 3.28 feet.
One yard	=	.9136	metre.
One foot	=	30.4794	centimetres.
One inch	=	2.5399	"
One square inch	=	6.4513	square centimetres.

Correspondence.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

SIR,—When you have made a mistake that possibly may do injustice to others, the only honourable thing that remains for you to do is to confess the error, and, if possible, undo the mischief that may have been caused.

"From information which we have received," but which it is not necessary to give in detail here, we believe we have done wrong to the Committee of Selection of the Exhibition in our letter of the 31st ult. We now believe that our pictures were treated with great consideration, and that we shall be well and sufficiently represented by those retained for exhibition. The fact is that we felt some natural surprise that those of our pictures which had received the most attention at other exhibitions should have been rejected as unsuitable for this, and, hearing rumours of similar rejection in the case of other contributors, it appeared to us that it was matter for discussion or explanation. The explanation, with which you are personally familiar, and can at your discretion make public, has satisfied us of the purity of the motives and the care exercised by the committee in promoting the general interests of photography.

ROBINSON AND CHERRILL.

SIR,—As an old photographer, and one who has seen something of the littleness of its votaries, when professional jealousy gives the clue, may I ask the complainants in respect of the numerous charges against the Committee of Selection of the International Exhibition, in the last numbers of your Journal—

1. Whether they are quite fair in so hastily complaining of secret motives and unfair bias?

2. Why, if these were the motives, could they not wait for better proofs than mere cowardly assertion of supposed competition?

3. Does it follow that, although these rejected pictures were good, there is sufficient space for all comers, and that the Committee have, in contempt of their credit, rejected the best?

Take half-a-dozen pictures out of twelve, chosen by six different individuals: what kind of agreement would there be in the selection?

Artists are not proverbial for being good judges of their own works, and why should not photographers allow their critics to differ from them, and believe that an invidious task has been honestly fulfilled, rather than seek in their own prurient minds for an unworthy cause?

4. May I ask if one of the "rejected" pictures is not a very old stager from a door-post in a fashionable thoroughfare, and is it quite fair to send pictures already so well exhibited to the International Exhibition? If so, we may expect all the man and woman traps from all the doorsteps of the great metropolis, which—

"Evil and good, have had their tithes of talk,
And filled their signposts then, like *this one* now."

Whatever excuse the owners of the rejected photographs may have for placing their complaints, there can be none for Mr. G. C. Wallich, in writing the concluding sentence of the first paragraph, and the whole of the last paragraph, of his letter. Probably, to use his own words, "I have formed my own ideas on the subject" as to the cause of his so writing; but that he should travel out of his way to insinuate charges against the Committee of Selection, before they had even commenced the task allotted to them, is a piece of unfairness that deserves the reprobation of every right-minded man, and of "photographers generally."—I am, yours faithfully,
April 11th, 1871. TRUTH BEFORE FAVOUR.

SPLITTING FILMS.

SIR,—As the films appear to have given unusual trouble of late, judging by the correspondence on the subject, every suggestion that may render this trouble less liable to occur will, no doubt, be welcomed. It is evident the causes are various.

Some years back, when using a well-known commercial collodion, I was much annoyed by the film splitting during development, and could only get rid of the annoyance by changing the collodion for another sample by a different maker. It was evident to me the collodion was here in fault.

There is, however, another cause I have seen suggested that may be worth repeating, as it is, I think, a common one. When a developer containing acetic acid and alcohol is kept for any length of time, or in a warm room, it is very probable that a small quantity of acetic ether is formed during its gradual decomposition; and, as this is a solvent of pyroxyline, the use of such a developer would be likely to induce rottenness in the film, and so render it more liable to be influenced by outward causes; when, therefore, large quantities of developer are made, it is a good precaution not to add alcohol till it is required for use.—Yours respectfully,

AN ARTIST AND OLD PHOTOGRAPHER.

VICTORIA CARD ALBUMS.

SIR,—Your over ready and kindly attempts to benefit photographers by the suggestion of novelties calculated to revive their languishing business are, I fear, too often baffled by the apathy of those to whom we naturally look to give them the necessary start.

The Victoria Card, already becoming popular in America and on the Continent, would seem to have no chance of an existence here. I have spoken with some professional friends in London. We all agree that the size is excellent, and that if it were introduced with spirit and unanimity, it could not fail to be at once fairly successful, and ultimately an established favourite. The album is the difficulty. I cannot find that any have been brought over from the Continent. Several manufacturers to whom I have written have given me the same answer. Messrs. M—— and Co. say:—"We doubt if the Victoria will be largely in demand; if it should, we shall at once go in for them." Perhaps it is hardly fair to say that in so doing manufacturers are putting the coach before the horse, because the manufacture of a new size of album on the large scale would necessitate new machinery, &c.

Now, if ten or twelve of the leading London photographers would unite to push the Victoria vigorously, there is not the slightest doubt that the want of albums would soon cease to exist. This is, perhaps, too much to expect. Those who are inclined, say, "Provide the albums, and we will do our best to bring the pictures into favour." The manufacturers say, "Create the demand, and we will supply the albums." And so the proposal shares the fate of every project which has the misfortune to stand between two stools.

Is there no remedy? I think I can suggest one. Let twenty or five-and-twenty photographers subscribe fifteen shillings each, and let them commission Messrs. De La Rue and Co., or any other respectable firm, to make forty or fifty albums, the best they can for seven-and-sixpence each, to sell at half-a-guinea. A very neat thing might be made for that sum (taking the quantity) at a profit to the maker. The apertures might be hand cut, and bordered with a plain line in gold. As to the backs, and binding the wide margin, carte size would do very well. Each of the subscribers would have two of these, and could then go to work with a will. If gentlemen who think well of this will forward their names to you, sir, and, when the number is made up, their subscriptions also, I would willingly undertake the arrangement with the manufacturer if no one else would care to do so. As a stationer, &c., I have had some experience in such matters. Perhaps you would kindly receive and pay the money. If this should set the ball spinning at the centre, I expect before long to see it whirling at the farthest provincial circles.—I am, sir, respectfully yours,
MIDDLESEX.

VICTORIA CARD ALBUMS, ETC.

SIR,—In your last number of the News there are two things I should like to say a word or two upon.

As regards the Victoria Cards, I introduced them here (Dalston) a few weeks since, and they have taken very well so

far. The great drawback, of course, is not being able to procure albums for them. When this is remedied, I think they will be very successful.

While on the subject of albums, I will mention an idea that has occurred to me. Some of my customers and friends keep a special album for the portraits of deceased friends; would it not be worth some manufacturer's while to make an album expressly for this purpose, with a black line round the opening, and crossed corners, like the Oxford mourning note-paper?

What "D. W.'s" question is, of course, I cannot exactly say; but there is one great objection to having a studio near a railway, unless the artist decides upon not taking children, or the trains run very seldom, and he has a time-table handy, and is careful to operate between the passing trains: the chances are that just as he gets a child in a happy position—which may have taken him some time and patience—the noise of a train, or scream of a whistle, will either frighten or attract the child's attention, and spoil it all.—Enclosing a circular, I remain, in haste, yours truly,

F. A. BRIDGE.

April 12th, 1871.

PHOTO-GALVANOGRAPHY.

DEAR SIR,—My aim in the present letter is to refer to the remarks of Mr. P. Le Neve Foster. The mentioned gentleman "reiterated his conviction that no plate was ever issued by Mr. Pretsch whilst with the Photo-galvanographic Company which was untouched by skilled hand-labour; and, further, that the process was incapable of producing presentable works without retouching." The first assertion is only partly, and the second quite, untrue, which I will show by the present statement, as well as by evidence of eyesight, if the mentioned gentleman himself, or anybody else, will come to Vienna, to show them the mentioned specimens.

In the last exhibition in London—where also many specimens of Mr. Fox Talbot, the Ordnance Map Survey at Southampton, and Mr. T. W. Osborne were present—I had exposed a great number of specimens, both for surface printing as well as for copper-plate. The "Venus de Milos," and some other ones, were situated in the fourth row, near the ceiling; other ones were placed on the side corner; and some ones—especially the most uncompromising ones for surface printing—were situated at the first glance. However, Mr. Le Neve Foster was the superintendent of that department, and he would, and perhaps has done so, overlooked the exhibited specimens at his leisure. Does he not know that I had worked with Mr. Dallas only about one year, and that I had more than seven years for my own use? Does he not consider that I had exhibited, at that time, almost all the new specimens which I had furnished during my stay in London of more than seven years, the time of my presence in London being almost nine years, and, altogether, it is now fifteen years?

Returning to my object in view, I wish to say that I had furnished a great number of surface or block-printing. Now I have before my hands thirty-nine impressions from blocks. These impressions are perfectly untouched, and twenty or thirty of them could have been used with some advantage. They are all from photographs; both one of them from an engraving in the same size as the original; some of them also from engravings, but of a considerable smaller size as the original; some of them from drawings smaller as the original; and many of them are taken from nature like an ordinary photograph.

Now I cannot perceive why these have not been mentioned at all at the meeting of the Photographic Society. The surface or block printing shows an immense advantage in its application. It is done in another way than the intaglio printing process. The mentioned specimens are not chosen for this purpose; on the contrary, they are quite from ordinary photographs, and some of them in too small a size. They have been printed at Messrs. Taylor and Francis's, at Messrs. De la Rue's, and at Mr. Clay's; and, if some of them look perhaps not quite in the manner like an ordinary wood engraving, it is quite naturally, because, at first, they are not such engravings; and at second, I must confess that I were in the beginning of printing from engravings like wood blocks not experienced enough. But, nevertheless, I have shown what has been achieved in reality. There has been not done anything nicer than the "Rocks in Wales," the "Rubens," the "Amphitheatre of Pozzuoli," "Hancock's Drawing of Cattle," the "Boy of a Paysant," "Venus Callipyge," the "Cathedral of

Strasburg," "Braco of Birds," especially for surface printing (the two last mentioned from originals of the larger sized specimens for copper-plate printing).

Coming to the specimens of copper-plate printing, I pray to say, that I know positively having at least exhibited two specimens not touched at all, viz., "The Venus de Milos," in the same size as the photographed original, and the "Drawing of Cattle, by Hancock." The first-mentioned plate now is in the hands of Mr. Brooker, Margaret Street, and the last-mentioned specimen is, I think, in the hands of Dr. Diamond. I had, for the purpose of showing the truth of what I have stated, shown the untouched copper-plate of Hancock's drawing in the exhibition, together with the touched copper-plate of the two birds, just to fit the contrast of the two plates, as well as of its treatment. Of Don Quixote, photographed by Mr. Lake Price, which has been touched and issued in the "Photographic Art Treasures," I had three impressions from the plate not touched at all, which are, in fact, nicer than the touched one. One copy of them I have sent to Paris, the second is in the hands of Mr. Fox Talbot, and the third is still not in my possession, but it is in Vienna, and I think to get it back again, just for the purpose of showing it. Mr. Fox Talbot can show, if he likes, the print to anybody; and if it were only to prove the difference of my method against his own. He made no use of the plate being raised, but traversed it by etching and similar processes into a plate to print from.

But still I have some more untouched plates which have been not at all publicly exhibited. There are five different impressions of untouched plates, partly published and partly not. There are also four different impressions of a fresco from Rome, "The Muse of Music with two children." Some trials have been done with it for the purpose of showing the difference of printing. Portraits of three ladies photographed from life, one touched by a clover engraver, and the other is untouched, which certifies the superiority of it over the first one. "Venus," by Raphael, which is very nicely done, but has been almost spoiled by some touchings which have been not necessary at all. One copy of a pen-and-ink drawing, by Albrecht Durer. Three copies of the portrait of Prince Albert, photographed from life, which I had the honour of showing to himself at Windsor; but, unfortunately, he died shortly afterwards. One copy of it is nicely touched, the other copy has been touched with pencil by the prince himself, and the third one is not touched at all, and I must confess that I prefer it to all others. Two copies of a drawing by Leonardo da Vinci; one copy is dirty, but still I have no other one of it; it shows the plate how it appears without any help whatever, and the second one is from the so-called "touched plate," which has been spoiled altogether. I had shown these two impressions to the head of the printing room in the British Museum, and he approved the untouched copy, but rejected with contempt the touched one. One copy of a drawing by Mr. George Richmond, which is very nice, but I think you have seen it already at Mr. Hogarth's. The "Venus de Milos," which has been mentioned already, and a copy of a painting of St. John, by Raphael, which have been not touched at all. Prince Albert, still living, furnished two copies of drawings by Raphael; one of them was very much faded and washed out, just for the purpose of showing the difference of it with the other one, which was exceedingly nice. It was done accordingly, but it did not look well, because the original itself was touched; but the second one, a large and very splendid drawing by Raphael, was done beautiful. I have four copies of it, all of them not touched at all. The first copy is of the reversed copy, and it shows pretty well what can be done in this way; the second and the third copy are of the same plate, one copy done with black ink, and the other one of the very same plate, done with a pale ink only, by the printer, Mr. Brooker. The fourth plate did not want this; it was quite like the original, and, consequently, is perfect in its beauty, and shows the superiority of my method over any of the other methods of reproducing drawings of high artists; in fact, it proves that no other method is in existence that may and can do this. This mode of reproducing such drawings will form, by degrees, an immense value to the art, and it will certainly surpass the present mode of doing those copies by photography only. All of the mentioned specimens are not touched, excepting a few of them which I have exceptionally mentioned, just to show the difference between touched and untouched.

It was especially in the beginning of the business of the company that touching was so much applied. However, I

have also some untouched specimens of this first period, twenty-one of them, published afterwards with the help of hand labour, which has been exceedingly expensive, being a new thing, and the artists in London taking advantage of it. They are taken from photographs; some of them I do not consider at all failures, and many of them could have been published with very little help by the artist. Besides these I have seven impressions of three pictures, untouched and touched by the artist: two copies of the portrait of Mr. Fenton; two touched and one untouched of a copy of "I pays," by Rejlander; and a large landscape of Mr. Fenton, touched and untouched, just to show the difference of them. Three copies of the envelope, St. Laurent's Church, in Nuremberg, and the Queen of England on horseback, which are almost untouched, an untouched faint plate of the first-mentioned picture being added. Five specimens are here done from a transfer of the plate from stone, which are very nice, but, nevertheless, I do not consider them of any great advantage for the future.

Now, moreover, there are twenty-seven specimens of various sizes which are touched but very little, and forty-one of them which have been published, and show to some extent the handwork of the artist. This can, however, be only be applied to works taken by photography from nature, which is necessary at least to put the sky in. In works from art it is quite impossible to apply handwork.

I know and have watched the progress of carbon printing; I know the different modes of doing photographs by lithography; and M. Albert's, in Munich, mode of reproducing photographs by printing from the photographic plates themselves is very ingenious, but does only answer to an experienced and very clever printer. These three modes of reproducing photographs would have never reached any degree of importance, if the mode of doing them by copper-plate or surface printing would have been applied in England. I can do this, and I am ready to do it again at any reasonable request.

Maps of whatever description, being like the ordinary engraved ones, or only designed in a somewhat other way, or being only washed by pencil and brush, I can change in a considerable short time into a copper-plate, to print from any number of copies, being hundred thousands or more.

Expecting to see Mr. Le Neve Foster, and, perhaps, some other Englishmen in Vienna, who are also connoisseurs of old drawings and prints, I shall receive them with every courtesy, and remain, dear sir, yours very faithfully, PAUL PRETSCH.

PS—I am now living, 1, Färbergasse No. 8, Vienna, 4 Stock (fourth floor), where I will be at home twenty-four hours after receiving a written application.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.

THE usual monthly meeting of this Society was held in the Architectural Gallery, Regent Street, on the evening of Tuesday, the 11th instant, Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of the former meeting having been read and confirmed, and the receipt of Transactions of the Astronomical Society acknowledged,

THE CHAIRMAN announced, with regret, that, owing to the illness of Mr. Hughes, confining him to his room, his paper on Experiences with the Carbon Process, otherwise quite ready for the meeting, must be postponed.

MR. DUNMORE then read a paper on Large Photographs, advocating, as a simple means of securing them, the production of large paper negatives from small collodion negatives. He exhibited several good prints on whole sheets of paper, and the paper negatives from which they had been produced. The original negatives were half plates. The specimens shown were produced by an amateur in the country.

A MEMBER asked for details of production, as Mr. Dunmore had referred to the operation as simple and inexpensive.

MR. DUNMORE, not having produced the specimens himself, did not know details. They were produced by the solar camera. Probably, if demand arose, persons would undertake to produce large paper negatives for the profession.

MR. H. BADEN PRITCHARD thought such work was a step in the right direction. No one could doubt that the charming small photographs of men like Mr. Gordon and Mr. England would, if enlarged to three or four feet, be very beautiful.

THE CHAIRMAN said, as a small photograph often contained

beauties too minute to be appreciated, the enlargement would often be very valuable. He should have been glad if some practical details of effecting this work had been given, and hoped that, on another occasion, Mr. Dunmore would be able to show to members that the process was as easy and simple as he had suggested.

After a vote of thanks to Mr. Dunmore,

THE CHAIRMAN showed a photograph of a port-wine bottle, in which the deposit or crust had been eaten into a curious design by, it was supposed, some caterpillar. He also showed some photographs of the recent eclipse by Lord Lindsay, and requested his lordship to furnish a few particulars of their production.

LORD LINDSAY referred to a few of the difficulties he had to encounter. First, delay and attempted extortion at Cadiz. Then, after transporting his instruments and equipment over very bad roads for twenty-five miles, he reached the desired position. The bad weather which ensued prevented observations whereby the instruments might be adjusted in a satisfactory position. The day of the eclipse having arrived, and everything being arranged in the best manner available, he placed two of his assistants in the dark room, one at the finder, another to pass plates to and from the dark room, whilst he himself exposed. He exposed ten or twelve plates during totality, and got six good negatives. About ten minutes before commencement, the sun became covered with a large cloud; fortunately, a vignette-like hole or rift in this cloud occurred, which just passed over the sun during totality, permitting the eclipse to be seen through it. Of the six negatives obtained, the longest exposure was twenty-three seconds. He hoped to show the photographic apparatus attached to the telescope at the next meeting. It was arranged so that it permitted him to get as many as seventeen to twenty negatives of the sun in a minute.

After a vote of thanks to Lord Lindsay,

THE CHAIRMAN called attention to the prize photographs of the Amateur Photographic Association on the wall, and, after a vote of thanks to the Association, the proceedings terminated.

Talk in the Studio.

PHOTO-LITHOGRAPHS OF MUSIC.—We understand that at the inauguration of the Royal Albert Hall, the copies of the music used by the singers and players, instead of being written by the old mode of taking out the parts of scores, were first photographed, then laid down on stone to be lithographed. The time and labour expended in the correction of written copies are now saved. Fidelity is secured by photo-lithography, as well as promptitude. We believe that the method of Mr. Griggs was employed.

MORE PIRACY OF PHOTOGRAPHS.—On Monday Mrs. Theresa Conroy, described as a photographer, and who had been apprehended on a warrant, appeared before Sir Robert Carden to answer a charge of infringing the Act 25 and 26 Vic., cap. 68, passed for protecting copyright in works of arts. Mr. George Lewis, jun., solicitor, conducted the prosecution; Mr. Merriman, solicitor, the defence. The prosecutor was Mr. Henry William Taunt, a photographer at Oxford, and he deposed, in effect, that he had photographed both the Oxford and Cambridge crews of the present year, who had respectively sat to him for the express purpose. He produced one of each of the photographs he so took, and a copy of the certificate of registration, which he had lodged in the proper quarter on the 9th of March, with the view to secure the advantages of copyright as to the Oxford crew, one of whom was thus described in it: "Mr. Payne, with his hat off." The copyright as to the Cambridge crew was registered in like manner, and the photographs of both crews were published by him in great numbers, and sold at 1s. each. On the 31st of March he bought, first five, and afterwards six spurious copies of his photograph of the Oxford crew, for 2d. each, in a court leading out of Little Tower Street, where the defendant and her son were selling them, and where he saw about sixty more on a piece of paper, and about as many again in a case. He also bought there a copy of his photograph of the Cambridge crew. After the warrant was granted for the defendant's apprehension, he went with a police-officer to 10, Bond Court, Wallbrook, an address she had given, and saw the officer take possession of nineteen more copies of his photograph of the Oxford crew. He had never given her nor any one

else permission to copy them. He had the negative still, and it had never been out of his possession. Being cross-examined, witness said he had registered six photographs of the Oxford crew from as many negatives, and worked them all; but in only the certificate of registration of one did the remark occur, "Mr. Payue, with his hat off." He had printed from all the six, and sold about 500 copies. The first day of publication he sold fourteen dozen at 1s. each. He afterwards saw the defendant's son at Putney selling pirated copies at 3d. each. Mr. Boydell Graves, son of Mr. Henry Graves, printseller, Pall Mall, proved that a warrant was now out for the arrest of the defendant's husband, at the instance of his father, for the infringement of copyrights in celebrated engravings vested in him, the "Railway Station," by Frith, being among the number. For the defence, Mr. Merriman complained of the manner in which the case against his client had been got up, and argued that a warrant should only have been issued where there was reasonable ground for believing that a summons would not receive the attendance of the defendant, which was not so in this case. He believed the law in this instance had been administered in an illegal manner, but, if not illegal, then in a way never contemplated by the framers of the Act. Mr. Oke, the chief clerk, replied that it was a matter entirely within the discretion of the magistrate to issue a warrant or a summons with respect to such an offence as that now charged. Sir Robert Carden commented upon the serious detriment and discouragement resulting to artists from a systematic piracy of their productions, and he fined the defendant £5, as he was empowered to do, for the first copy sold, with the alternative of two months' imprisonment, and £3 each for the other ten copies, with the alternative of twenty-one days' imprisonment, which would be cumulative. The fines amounted in all to £35. Mr. Merriman intimated that he would appeal against the judgment to a superior Court.—*Times*.

To Correspondents.

TROUBLE—We fear very much that with the studio you describe you will always have trouble. It is neither built nor arranged in accordance with advice we have very repeatedly given for years past. A south-east aspect must always be more or less troublesome, as the quality and strength of light must be perpetually changing. But two thicknesses of calico used to keep out direct sunshine must inevitably deprive you of almost all the light. If you cannot have any other aspect, you must be prepared for constant care and management. Instead, however, of using two thicknesses of calico to intercept direct sunlight, use one thickness of tracing-cloth, or a thickness of tissue-paper stretched on a frame; or slightly dull the glass through which the sunlight constantly pours, by means of starch. Any of these will sufficiently break the direct rays, without stopping out much light. Your room is rather low and narrow. Green is a bad colour for the walls, and blue-and-white-striped blinds are unwise.

MELBOURNE.—Under the circumstances you describe, you appear to have a perfect right to sell the prints. The original drawing may be copyright, in which case a question might arise; but if you have had permission to sell photographs of it for years undisturbed, it seems improbable that your right can now be disputed. The portrait of a dead child is very pretty and successful indeed.

G. BARRETT.—The yellow spots are due to imperfect fixation at the points in question, probably caused by the formation of minute air-bubbles on the print whilst in the hypo bath. These bubbles prevent the perfect action of the bath at these points, and cause yellow spots of imperfect fixation, which do not show generally until after the print is washed and dried. 2. The tone is good. 3. We are unable to recommend any especial manufacturer. 4. We cannot with certainty speak of the probable success of the cameo vignettes. So far as we have opportunity of judging, they will become popular, and we think they deserve to do so. 5. The example you enclose is very good. The figure is slightly too low in the oval, however.

SEMPER VIRENS sends us the following advertisement cut from a provincial paper:—"Important Notice.—Professor Simpson, from the London Photographic Society, is erecting a first-class photographic studio in St. John Street, —, which will shortly be opened. The Professor intends to open his establishment in the London style, and at London prices, which will be announced in future advertisements. Photography in all its branches, with all the latest improvements. By strict attention the Professor hopes to gain a liberal support." Our correspondent asks, "Can this really be our respected Editor?" and wishes to know what are London prices. We need scarcely inform him that we know nothing of the matter. We hold no professorship; and there is not, and, so far as we remember, never was, a Professor Simpson connected with the Photographic Society.

A. Z.—The simple ridge-roof form of studio is best. The size depends much upon your choice or necessities. The following are good proportions:—Length, 26 feet; breadth, 12 feet; height to eaves, 8 feet; to ridge, 14 feet. The principal side-light from the north; on north side and roof all glass, except five or six feet at each end; the glass need not come within 18 inches of the ground. No glass is necessary at either end or on the south side or roof, but a small portion of glass on south roof may be at times convenient; but it should be kept covered with blinds when the sun shines.

F. S. M. (Bedfordshire).—Varnish may be filtered either through soft filtering paper or cotton-wool, taking care to put a plate of glass on the top of the funnel to prevent evaporation. We prefer, however, to let varnish stand to settle well, and then to decant off the clear portion. It is wise, also, to pour from one bottle, and pour back into another, so that the stock of varnish for immediate use may be kept clear, and free from particles flowing back from the plate. 2. The reason that you have fewer negatives break now that you are using old cleaned plates coated with albumen is doubtless due to the fact that the plates have been before tested and found flat, whilst amongst new plates some will occur which are not so. Your plan of using two glasses is useful in improving the gradation.

J. A. D.—Mr. Durand's method of preparing his sensitive paper so as to keep some time without deterioration is a trade secret, with which we are not acquainted. We have recently published the best generally known method of keeping sensitive paper.

SIXTH VOL. sends us details of an irritating kind of competition to which he and others in his neighbourhood have recently been submitted. He says:—"Knowing you to be an advocate for remunerative prices in photography, I write to state a piece of what I consider unfair practice now being adopted by a provincial firm, which may be considered legitimate by some business people, but which I consider deserves a different appellation. Some three or four years ago the said firm sent an operator here to obtain a set of view negatives, and, as soon as they were ready, they offered them to the non-photographic shopkeepers at 3s. per doz. cartes, 6s. per doz. stereos, to sell at 6d. and 1s. respectively, and which was respectively 6d. and 1s. lower than photographers had supplied them before. On calling upon my customers at that time, I was informed of the reduction, and told that if I would supply my views at the same prices I should be dealt with by them. I, with others, bowed to my fate, trusting to the merits of my productions to secure custom, a result which has followed, my wholesale business having gone on satisfactorily increasing. And, in consequence of our rivals finding their orders becoming so small, their authorised representative, on his last visit here, disgusted with the smallness of the accounts, plainly told his customers that unless they gave orders as formerly to a respectable amount, that they (the firm who sent him) would push their goods into any and everybody's hands, such as greengrocers, &c., and at such prices as would enable them to sell cartes at 2d. and stereos at 6d. each, so as to cut up the trade. I am sorry to state that some here were intimidated into giving larger orders through those means, and, consequently, we local photographers suffer accordingly. Can you advise any means by which we may prevent photography being so degraded? In some other towns I am informed their customers refusing to be intimidated, they actually carried their threat into execution, and eventually gained their ends. Now, can nothing be done to stop such proceedings, to prevent them bullying their customers into their own terms, to the detriment of local tradesmen, with threats of ruining the photographic profession in the place? We made the best of fair competition, but, when such means are resorted to, I think we are called upon to bestir ourselves. Could not the photographers in other towns the firm have "done" be induced to join hands and support each other in such a matter? Is there not sufficient *esprit de corps* amongst them to make a stand against such practices? Can you assist us in putting us in the way of communicating with each other?" The circumstances described are sufficiently mortifying, and the conduct of the firm in question, in our estimation, is as unwise and suicidal as it is injurious to others. We regret, however, that we do not see any method whereby such under-selling can be prevented. The best plan is to excel them in quality, instead of attempting to compete in price when they sink below what is fair or remunerative. The examples sent are very good.

C. G. E.—Any photographic dealer will, doubtless, supply you with crucibles; or, possibly, you may be able to procure them of a local chemist. We cannot tell you the exact prices; but they are not expensive.

R. SLINGSBY.—We coincide with your decision.

ADAM DIXON.—Thanks. In our next.

F. NEWBURY.—There is no manual on the subject of enlarging by line light. The back YEAR-BOOKS are almost all out of print. The present has been sent. Various numbers of the NEWS contain articles on enlarging by artificial light.

W. H. BADEAU.—Many thanks.

Several Correspondents in our next.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

It will gratify our readers generally to learn that, all difficulties and doubts to the contrary notwithstanding, the display of photography at the forthcoming International Exhibition promises to be fairly representative and decidedly satisfactory. During a recent visit to the Exhibition in its present embryotic and chaotic state, we were very agreeably surprised to find the completeness in every respect of the photographic department. The various portions of the Exhibition buildings are, as many readers know, scattered about the grounds of the Horticultural Gardens; photography, however, in conjunction with water-colour drawings, engravings, and other fine art products, finds a place in the handsome gallery which runs round the Albert Hall. Although the position necessarily involves the ascent of many steps, no more favourable or attractive locality could possibly have been chosen for light, space, and convenience; and no place more favourable for publicity, as the gallery in question must inevitably be visited by almost every body, not merely for the purpose of inspecting its fine art contents, but as presenting the finest view of the very noble hall, which far surpasses in grandness of proportions, symmetry, and general harmony of effect, the majority of the descriptions which we have met with.

Before referring further to the photographs, it may be well to advert to a subject the discussion of which has occupied some portion of our columns during the last few weeks, and in relation to which we are asked in the present number for specific explanations with which we are familiar. The Committee appointed to make a selection of the worthiest examples of photography to fill the space available, having completed their work, at once notified photographers that they might withdraw the contributions not found worthy, or for which there was insufficient space. The inevitable disappointment followed: similar disappointment always has followed, and probably always will follow, on similar occasions. Many contributors felt disappointed that all their pictures were not retained, and others discovered that the rejected contributions were the very pictures which themselves and their friends had most highly admired. The care and capacity, or the motives, of the Committee in such cases are at once suspected: their judgment is at fault, or some sinister motive is at work. This kind of dissatisfaction is probably very natural, it is certainly very common. We know something personally of the thankless character of juridical labours in exhibitions of this kind: hard and anxious labours are rewarded at times by hard and virulent abuse, generally by distrust, and rarely or ever by gratitude. In this case, however, the rumours of dissatisfaction assumed a more specific form, and it was distinctly suggested that one of the Committee

who had attained a very high position in the most artistic branch of photography had suppressed the works most likely to compete with his own productions. All these rumours prove, on a little examination, to be utterly groundless. The letter of Mr. Peter Le Neve Foster in our present issue satisfactorily explains and justifies the general position of the Committee; but we may add a few further comments, the result of personal investigation and enquiry, in order to show that the principles which directed the selections of the Committee most conduce to the interests of photography and photographers, that their work is thoroughly well done, and that rumours of personal motives are altogether without foundation.

To dispose of the latter point first, it is simply necessary to state that the Committee do not exhibit at all. That the interest of the Exhibition would have been greatly enhanced by the display of some of Dr. Diamond's photographs, unsurpassed in their special branches, and by some of Col. Stuart Wortley's grand sea and cloud pictures and large portrait studies, there cannot be a doubt; but there cannot be less doubt that, in refraining from exhibiting, these gentlemen take the highest and most unchallengeable position, and become, like Cæsar's wife, not only pure, but beyond suspicion.

In doing justice to photography and photographers, the Committee had three considerations in view: they had to secure excellence, novelty, and a fair distribution of space; and their general aim would not have been secured by the sacrifice of any one of these considerations. We believe that, as a rule, little difficulty was experienced in relation to the first. Photographers generally sent their best work, and much good work was contributed. Too often, however, the element of novelty seemed to have been altogether disregarded. In many cases the pictures sent in had been displayed at every exhibition held for a year or two past; many had been published, advertised, and sold largely; some had been in show-cases, or used as advertisements. The justification offered by the contributors of such pictures we know will be, that novelty was not made a condition of acceptance, and that if it had been, the long unfavourable season would have rendered novelty absolutely unattainable. It should be remembered, however, that whilst the absolute novelty which will be demanded in the subsequent annual exhibitions of this kind was not made an imperative condition here, yet novelty is at all exhibitions a desirable, if not an inexorable condition, and that of two pictures equally excellent, that which was new, or, if not new, that which had been least frequently exhibited, would be selected. That the importance of sending new pictures has not been appreciated by many photographers is tolerably certain; but after a very little reflection it will be clearly seen that the exhibition of old and familiar pictures must completely defeat the end of the contributors themselves. Visitors to

the photographic department seeing a number of pictures with which they were familiar would quickly lose interest in the display. The press critics generally, from whom, at an exhibition of this kind, exhibitors hope for notice, seeing pictures which they had noticed at other exhibitions, would pass the matter by as stale, and, therefore, without interest. For these, and a variety of other tolerably self-evident reasons, some degree of novelty becomes a condition of vital importance to photographers themselves, without stipulations from the authorities. Absolute novelty was probably impossible this year, and it was not made a condition, as in future years it will be; but wherever it could be found combined with sufficient excellence, it was a recommendation which secured the selection of the Committee. We may add another hint to photographers: novelty and excellence in some cases fail to secure pictures a position if these qualities are spoiled by the introduction of the trade element. We understand that some of the rejections were due to the fact that the contributions were clearly trade advertisements, and nothing more.

The best justification of the Committee will be found in the accomplished fact. Within a fortnight the display will be open to the public, and we shall not anticipate by entering into details now. We may remark, however, that we feel sure that those gentlemen who have been induced, by adverse rumour, to express doubts, will be perfectly satisfied with the result as it stands. We repeat, that the collection of photographs is a very fine one indeed, well selected, and admirably hung. There are five bays or panels devoted to photographs, each about twenty feet wide by sixteen or eighteen feet high, and in each of these are hung, in very effective order, from sixty to seventy pictures, all more or less excellent, some very fine indeed, and many of the best quite new. We miss the works of some we should have liked to see present; but, on the whole, the selection is admirably representative, as well as of great excellence, and the general arrangement leaves nothing to be desired.

THE WET PROCESS WITHOUT DARK ROOM OR TENT.

It can scarcely be doubted for a moment that if the wet process could be worked in the field as easily as dry plates, and involved as little trouble in packing and carriage of appliances, dry-plate photography might, except for very special purposes, soon be numbered amongst the extinct arts. Repeated attempts have been made to render the wet process possible without a tent, and many ingenious contrivances have been devised to permit the preparation of a plate, and its transport through its various phases until it emerged as a negative, under perfect shelter from light; and some of these have had so much promise that we have been surprised that they have been received with so little attention or favour by the photographic public. Tents, manipulating boxes, and manipulating cameras, all possess the cardinal objection of involving troublesome package, bulk, and weight, and, worse than these, of involving much discomfort in manipulating. With the head enveloped in a hood, as in Archer's camera, the arms both engaged inside a box, and held there with sleeves, or the whole figure inside a small tent, there are many discomforts and inconveniences besides the risk of being attacked by the bull, which was once supposed to be the landscape photographer's *batte noir*. But in spite of these things, the seductive faculty of the wet process, the charm of knowing the quality of the negative just exposed, the opportunity of trying again when any form of defect is noted in the negative; these, and many other advantages, induce many photographers to bear the fardels of the wet process, and groan and sweat under the weary load of impedimenta it involves.

The very ingenious combination of camera, baths, and protecting plate carrier, described some years ago in our pages by Mr. Barrett; the photo-camera-hutch, a some-

what similar arrangement, described more recently by Mr. W. Whiting; the miniature apparatus of Dubroni; and some similar contrivances for working wet plates in daylight without a tent, have failed to impress photographers with their practicability; from what cause we cannot precisely say; but, so far as we can judge from expressed objections, chiefly on the ground of the possible contact between the silver bath and the developer, being conveyed by the portions of the apparatus holding the plate. That such a danger was by no means a necessity we are satisfied, if ordinary care were used in the operations, the experiences of Mr. Barrett, a trustworthy amateur, and that of Mr. Whiting, both bearing full testimony to this fact. But fear of this, fear of the trouble of the operations, or of the apparent complications of the apparatus, or of other undefined troubles, have served to prevent the contrivances coming into use.

Mr. Edwards proposes to effect the desirable end in question by simpler contrivances than those hitherto proposed, and by means of apparatus sufficiently efficient to silence all objections, and captivate the most indifferent or unbelieving. There appears to be neither difficulty nor risk of any kind in the system of working he proposes. The new appliances consist of a silver bath and a developing bath. These, and a new camera back, are all the new apparatus required. The silver bath consists of a flat bath of well-seasoned wood, lined with a neutral water-tight material, having at one end a well containing the nitrate of silver solution. A plate having been coated and placed in the flat bath, is protected from the light by the new camera back, which slides into a groove so as to cover the flat bath. The solution from the well is suffered to flow over the plate, and remain a sufficient time to excite the film properly. The bath being then placed in a vertical position, the solution flows back into the well, and the plate is left a few seconds to drain. A very clever contrivance in connection with the apparatus next comes into play: the bottom of the flat bath consists of a sheet of pure india-rubber, which, being elastic, permits the plate to be pushed forward into the camera back, the slide of which has been withdrawn to permit the plate to be passed into it. The slide is again closed, and the camera back containing the excited plate withdrawn, which, having been exposed, is ready for transfer to another flat bath for development. This, also, consists of well-seasoned mahogany, rendered neutral and water-tight. Its bottom consists of non-actinic glass, and it has a sliding cover of non-actinic glass. The camera back having been placed in a groove over the dish or bath, the yellow glass top is withdrawn, and the slide of the camera back being also withdrawn, the plate drops flat into the bath. The yellow glass cover is now again closed, and the camera back removed. At the side of the flat wooden bath is a cell, into which a developer is poured. This cell is ingeniously arranged with an aperture formed of a double elbow or zig-zag, which a fluid can readily flow over, but which is an effectual protection from light. The developer is thus easily made to flow over the plate, and, as top and bottom of the bath consist of yellow glass, there is no difficulty in watching the process of development.

The developer used by Mr. Edwards is that he recently described in our pages, consisting of a few drops of a concentrated solution of sulphates of iron and copper, added to a solution of acetic acid, alcohol, and water, the two being mixed when required. The peculiar characteristic of this developer consists in its deliberate action permitting time for watching the precise result required. When the negative is seen to be sufficiently developed, the iron solution is poured off, and a little of the acetic acid and water applied, which at once effectually arrests development. The plate can then be removed from the bath in daylight without risk of injury, and can be placed in the box without washing, to be dealt with at home at leisure.

The simplicity, compactness, and efficiency of the apparatus, and of the operations, appear in all respects to leave nothing to desire. Mr. Edwards has produced a negative in the dining-room of our residence with perfect ease and perfect success, as he also produced one before the South London Society by the aid of the magnesium light. With ordinary care there appears to be neither risk of stain nor failure, all the operations being as easily and safely practicable in a sitting-room as in the open field. There is no risk of injury to or contact between the solutions, and everything appears under control as perfect as that obtained in working in a dark-room, so that amateurs at home, as well as in the field, will find the new apparatus a very valuable accession to the operating facilities.

OBITUARY.—T. R. WILLIAMS.

With very deep regret we have to announce the death of one of the oldest and ablest amongst the veterans of photography, our task being rendered more painful and difficult by the fact that in doing so we have to speak of the loss of a very highly esteemed personal friend. On Wednesday week, in the forty-seventh year of his age, Thomas Richard Williams, of Regent Street, died at his residence, Sellers Hall, Finchley. Just two years ago Mr. Williams, who had been for some time in imperfect health, was stricken down by serious illness, which rendered his immediate and complete retirement from business imperative, his disease being pronounced incurable, and even temporary prolongation of life depended upon perfect rest and constant care. These conditions being at once secured, partial restoration followed, the two years which have elapsed since having been marked by interchange of hope and fear, recovery and relapse, general weakness increasing until the end came.

Mr. Williams was one of the earliest photographic portraitists, his connection with the art commencing immediately after his birth, upwards of thirty years ago. In the year 1840 M. Claudet commenced professional portraiture by the Daguerreotype process in London, and shortly after he commenced, Mr. Williams, then a youth in his seventeenth year, entered his establishment, the especial duties for which he was intended being those of book-keeper and assistant in the reception room. Very soon, however, his skill and taste led him to take part in the operative and artistic departments of the establishment, and he developed a rare talent for tinting Daguerreotypes with the powder colours then just introduced. After spending a few years in M. Claudet's establishment, and acquiring high skill in different branches, he left, and was for a time successfully engaged in the studios of Beard and Henneman. It was in West Square, Lambeth, where, in a modest way, Mr. Williams had commenced business on his own account, that he first obtained the attention of the art world as a photographer of very unusually fine taste and skill, Sir Charles Eastlake, then president of the Royal Academy, being one of his earliest patrons. From this time his career began to be one of rapid and complete success; the unpretending little Lambeth Square being not unfrequently blocked with a dozen carriages awaiting the visitors at Mr. Williams' studio. About seventeen or eighteen years ago Mr. Williams removed to Regent Street, where he built a studio, the excellence of his results and the success attendant thereon having in no wise declined. Two years ago, when his health failed, he was joined in partnership by Mr. W. Mayland, of Cambridge, a gentleman whose delicacy of taste and especial skill accorded in a singular degree with the qualities which had attained for Mr. Williams such a high position in the ranks of photographic portraitists. The Regent Street establishment was thus enabled to maintain, without diminution or change, its prestige in the special branches of portraiture in which Mr. Williams had for years stood *facile princeps*.

The chief influence exercised by Mr. Williams on photography consisted, not in making discoveries or initiating novelties, not in communications to societies or articles in journals, but in the force of a great example. His produc-

tions were always something to work up to, and for many years seemed to present to the majority of portraitists a pinnacle of excellence altogether unattainable, dependent upon occult causes, the arcana of which were impenetrable. Mr. Williams was, however, an originator. To him, if we are not mistaken, photographers are indebted for the simple suggestion of iodizing the nitrate bath, instead of spoiling the first few plates immersed into the uniodized solution. He was the first also to produce the charming subject stereo slides which had at one time such a rage. Groups and rustic scenes, often combined of properties arranged in his studio, yet managed with such consummate skill and feeling for nature that, even with the searching scrutiny of the stereoscope, no discrepancy or lack of truth and keeping was perceptible to the closest observers of nature. First in Daguerreotype, and afterwards on paper, these charming studies had for a time a high popularity, and it was only when the same class of work became vulgarized by imitation, and scarcely remunerative from competition, that it was abandoned by Mr. Williams, in order to devote himself more completely to his especial forte, portraiture, in which he attained a higher and more remunerative success than probably any of his contemporaries. The Daguerreotypes of Mr. Williams were distinguished by the combination, in their highest possible forms, of brilliancy and delicacy; and precisely the same qualities distinguished his paper pictures. The especial class of portraits which have been associated with his name for years is the whole-plate vignette, generally consisting of head and bust only. These were always remarkable for the singular roundness and perfection of the modelling, the solidity united to exquisite delicacy, and the perfection of the vignetting. As a rule, his work possessed, in virtue of excellent lighting and skilful photographic management, the rich delicate modelling with which photographers are now familiar as the result of retouching the negative. A fine perception in selecting always the most beautiful aspect of a head, and an instinctive knowledge of the treatment and arrangement which would render it at once the most picturesque and characteristic, were also amongst the essential elements of his success and reputation.

Great excellence and complete success in any art generally depend upon a combination of qualities; but, probably, to no one quality did Mr. Williams owe so much of his success as his exquisite delicacy of taste, his fastidious demand for faultlessness within the range of his perception. No result was good enough which was not the best attainable. In a business returning five or six thousands of pounds per annum, rarely a picture was permitted to be sent out which had not passed under his eye. We have seen him throw aside ten out of a dozen whole-plate vignettes sent in by the printer, in which scarcely any fault was perceptible; but the shape, gradation, or the extent to the eighth of an inch of the vignetting did not come up to his standard, or the precise depth or tint might be improved; and if improvement were possible, the print was ruthlessly condemned. This precision and fastidiousness of taste governed the whole of his work. No anxiety to do business would induce him to try sitters in bad light, when good negatives were impossible. The issue of such a course is instructive: few portraitists have ever attained such high rates for their work, or have had such an extensive first-class connection.

To skill, precision, and taste, Mr. Williams added singularly winning and graceful personal qualities. Gentle, conciliatory, and amiable, he everywhere created a favourable impression. A keen lover of nature, of poetic temperament, and contemplative habits, his chief pleasure beside photography and art consisted in horticultural pursuits. The loss to photography and to his friends is great, and it is scarcely mitigated by the reflection that success induced—as it should not do, but too often, alas! does—too close, too anxious, and too protracted attention to duty, and too much neglect of personal comfort, rest, and restoration, and thus cut short in its prime a life that might have been long, happy, and useful.

THE "EDINBURGH REVIEW" ON
PHOTOGRAPHY.

AN interesting, but scarcely sufficiently accurate or comprehensive, article on the "Applications of Photography," appears in the number of the *Edinburgh Review* just issued. In making some extracts from the article, we shall incidentally point out some of its omissions or errors, without undertaking, however, to supply all its shortcomings. At the outset we may remark that in any sketch of the history of photo-mechanical and permanent printing processes, and of their present applications, it is singular to miss the names of Poitevin, Osborn, Swan, and others, and very odd to find omission of all allusion to the processes of Dallas, Albert, Fruwirth, and others who have been working of late years with such assiduity and success in combining the capacities of photography and the printing press. The writer commences by remarking that "any real scientific discovery, however barren in practical bearing it may appear at the moment, is certain, in the long run, to lead to many other inventions, and to set in motion other appliances, which heretofore only seemed to be awaiting the new influence. The machinery, so to speak, rests idle for the want of some cog or spring to complete its action. Among the more recent examples of a latent want, the supply of which has given a start to many a new art, and has revolutionised others, may be considered photography. The instantaneous draughtsman, ever ready, working with absolute truth both by night and day (for by the addition of highly sensitive paper the aid of the sun can now be dispensed with), catches and registers the scientific data of the astronomer, and the meteorologist, seizes the wonders, and renders patent to the eye the hidden world opened up to us by the photo-microscopist; and where there is excess of light which blinds the human eye, Sol paints himself with his own beam, with lineaments so accurate from day to day, that the scientific watcher is only now beginning to discover the changes that are taking place in the great luminary.

When Fox Talbot and Daguerre simultaneously discovered the power of the pencil of light to paint an image on a tablet as quickly as it flashes upon the retina of the eye,* great were the predictions of the part the new discovery would play in the field of science and art; but the wildest anticipations have already been surpassed in less than forty years since the original discovery, and every day is adding to the number of the wonders it is opening before us. It is our purpose, in this paper, to sketch, with a light hand, the many valuable arts and the curious appliances which this beautiful discovery has suggested to the scientific worker, the artist, and the manufacturer. So rapid are the changes, and so great, from day to day, are the improvements, that we can only treat it as a progressive art, capable of almost unlimited extension."

After commenting on the fact that the photograph in silver contains within itself the elements of its own destruction, he proceeds:—

"It may easily be conceived that Mr. Fox Talbot was fully alive to this shortcoming in his great invention, and, as long ago as 1852, was anxious to find some means by which permanence could be given to sun-pictures. In casting about to find some means by which engraved plates could be taken directly from the photographic negative, his attention was directed to a discovery made by Mr. Monge Ponton a short time before, apparently by accident, that bichromate of potash became darker in colour when exposed to the light. The photogenic quality of this salt at once struck his acute mind as the means of solving the problem. After many experiments he found that bichromatized gelatine or gum, upon exposure to

light, became insoluble in water, and that a plate could be prepared with this material, from which all those parts debarred from the light might be dissolved away. This discovery was the germ of numerous allied processes which have revolutionized the engraver's art, and which cannot fail to have a most important effect upon the illustrations of our literature, and, indeed, upon pictorial art generally, inasmuch as we need no longer depend upon line engraving, woodcutting, or lithography, nature herself reproducing her own drawings at a cost infinitely less than we have hitherto paid for inferior productions of the human hand.

"Among the numerous patents that have been taken out of late years for utilising by this means the sunbeam as an engraver, we name, as practically established, the different processes known as Autotype, Woodburytype, and Heliotype. We wish to refer to these three processes first as the only ones capable of giving, with commercial success, copies of photographs, pictures, and drawings whose delicacy of *half-tone* in a graduated tint is their chief beauty, and this cannot be produced with equal success by line engraving, lithography, or mezzotint."

The process of photo-relief printing having been described, the writer goes on:—

"Already some excellent specimens of its work have issued from the press, among which we may mention 'Viardot's Wonders of European Art,' which contain sixteen impressions by this process, with eleven woodcuts—and the contrast between the two is sufficiently striking to even the uninitiated in art. 'Crossing the Stream,' by Claude, gives the golden haze of the Italian distance with a delicacy which is perfectly unapproachable by any system of engraving, whilst the shadows possess a depth which leaves nothing to be desired. Again, the copy of Vandyck's noble portrait, in the Louvre, of Charles I., habited in Cavalier costume, is an exquisite example of its power to render the tenderest details and the most powerful shadows with wonderful effect. The ink used—or, rather, we should say, the pigment—is of a very warm, dark chocolate tint, and of a flowing character, which gives a rich glow to all the shadows, contrasting powerfully with the harsh blacks of the woodcuts in the same volume. The small expense at which these delicate copies can be made will, we fancy, give the process a great advantage in the illustration of books. The only drawback, as far as we can see, to its being applied to cheap literature, is the necessity to mount the prints upon card or other stiff paper, their borders being destroyed by the nature of the process, which, as we have before stated, spills all the superfluous ink over the margin, consequently trimming and mounting are necessary. Unless this difficulty is overcome, we fear the process will be confined to the more expensive class of works. At the present moment, the size of the prints produced is limited by the size of the hydraulic press, which is comparatively small; but we understand this size is about to be increased.

"The action of light is necessary to produce the chemical effect upon the bichromatized gelatine, but efforts are being made to accomplish this by artificial means. The company working this process have been employing a powerful electric apparatus, worked by a gas engine, which gives a speed of 400 revolutions a minute to a revolving armature, which rotates inside a number of permanent magnets, and yields a light of great intensity. It is far, however, from being a substitute for the solar ray, inasmuch as, whilst a good impression from an ordinary negative is produced by the former in ten minutes, the electric light requires three hours to yield the same result. But this is an advance upon the lime-light, which necessitated an exposure of even double this time. In the dark winter weather, when the sun is sometimes hidden for weeks, there can be no doubt the electric light will find constant employment. In night-work, again, it will be ready, thus affording employment upon works which otherwise would be delayed for want

* It is, perhaps, somewhat hypercritical to point out errors of exaggeration, but it is not a fact that this rapidity was so discovered. The Daguerreotype, as discovered by M. Daguerre, required an exposure of some minutes; and the simultaneous discovery of Mr. Talbot was not more rapid. The discovery of the instantaneous possibilities of photography was due to subsequent labours.—ED. PHOTO NEWS.

of daylight. Already several works have been illustrated by the Woodburytype process, and are familiar in our drawing-rooms; the pictures are easily mistaken for photographs, and are far more delicate and effective than the best steel engravings, at a cost almost nominal; a good-sized picture being reproduced at less than a fathoming a copy. After a long struggle with many difficulties, this method of reproducing the most delicate drawings, photographs, &c., may be considered a commercial success, and we cannot doubt that it will have a material effect upon the engraver's art, which, with some limitations to be mentioned hereafter, it must in course of time greatly supersede.
(To be continued.)

A FEW HINTS WORTH KNOWING.

BY W. T. BOVEY.

AN interesting leader, treating on the intensification of negatives, which appeared in the NEWS of last week, reminds me that I have hitherto omitted publishing particulars of a method of strengthening fixed negatives, which for several years I have practised with unvarying success. The process in its general details is by no means novel; there is, however, a notable point of divergence from the original, which will, probably, be regarded as worthy of attention, and to which, in due course, I purpose directing attention.

Occasionally I receive from customers parcels of negatives in an unvarnished state, accompanied with a request that, if requisite, they might be further intensified. But, in addition to a lack of the proper strength, I perceive in some of the negatives sent me, that deficiency of detail which is common to all under-exposed plates; and to remedy the defects as far as after-treatment is capable of effecting, I proceed as follows:—

First. With a small brush I lay on a rim of varnish around the four edges of the plate, to guard against the possibility of film slipping during subsequent operations. I then proceed to loosen the pores of the collodion surface by flooding it with water. Draining the water off, I replace it with a two-grain solution of iodide of potassium, and allow this to remain on the plate about one minute. This last operation I execute in the dark chamber. I then expose the plate to daylight for two or three seconds, and wash the iodide solution thoroughly off. A pyro solution composed of—

Pyro	2 grains
Citric acid	3 "
Water	3 ounces

is then poured on and off the plate, when a drop or two of a 20-grain silver solution is added to the redeveloper, and the intensification is proceeded with in the brightest light available short of direct sunshine.

The results are often surprising: details before invisible come strongly out, and the negative gains in printing strength very rapidly. In some instances it is advisable to go through the whole of the operations as I have described them a second time, but recourse to this available contingency is not often needed. For instantaneous photography this mode of strengthening negatives would prove of considerable value. I scarce need add the caution that the negative must be fixed prior to its being subjected to the treatment.

A word respecting the novel point to which I have before alluded. I convert the surface silver into an iodide in the dark room; the usual custom observed is to perform this operation in open daylight. By the adoption of the last described course the iodide of silver loses those magnetic properties by which reduction of the silver salt is so materially aided. The force of this remark will be best understood by a thought being directed to the result which follows a prolonged exposure in a very intense light. Beyond a certain point of exposure iodide of silver must certainly retrograde in its powers of magnetic attraction. By applying the pyro and silver to the plate in solar light

we secure actinic aid to effect reduction on the weaker parts of the negative. A negative must be very weak indeed which remains uninfluenced by the treatment I have described.

Apropos of weak negatives, a method of producing comparatively vigorous prints from such will doubtless prove of interest to those who require such information. Medium Rive's, coated with a fresh and full-bodied albumen, is preferable. Float the paper not less than seven or eight minutes. Print in very diffused light. If the negative is one of extreme weakness, print through a sheet of white—or, what is better, a sheet of lemon colour—paper. This should be fastened on the outside of the frame, and at some distance from the negative. The picture should be printed deeper than would be required with a stronger negative. Tone the prints in a weak gold bath, and, whilst toning, keep the picture side uppermost. This remark includes a hint worth noting, as a brilliant print and tone can often be secured in the way advised, when nasty flatness would result from toning the printed surface downward. It is worthy of remark that prints tone much more rapidly face down than when the picture side is kept upwards. Those who are in the habit of toning in batches with strong gold baths would do well to observe this hint, and tone the earlier lots of prints face uppermost, a precaution which would ensure a greater uniformity in the colour of the prints they produce.

Writing of prints reminds me of a singular bit of experience recently related to me by a very intelligent photographer, Mr. Middlerness, of Kelso. For a considerable length of time he had been troubled with, and had suffered much pecuniary loss from, metallic spotting of his prints. He consulted his photographic friends, and faithfully tested each remedy they prescribed, but success lay far beyond. At length, in forlorn hope, he changed his toning dish. *Eureka!* the plague ceased from that moment. On reflection, he remembered that the offending dish had been frequently used in the operating department, and doubtless the crack-like, unglazed portions of the porcelain had imbibed the reducing agents, which subsequently attacked and spoiled the prints. Without doubt Mr. Middlerness has provided us with an additional illustrative argument to prove that on little points, for weal or woe, important results very often hang.

The season advances apace when amateurs, with tent and satchel-camera, will be roaming amid the picturesque of hill and dale in quest of those little "rustic bits" which every admirer of rural nature loves so fondly. Let me advise those ardent hunters to add to their takings a few good cloud negatives, as the process of combining natural clouds with their pictures is a more simple operation than is generally supposed. The way to do it I briefly describe.

The sky portion of the picture must, of course, remain, in the onset, white. With a clear horizon, where no buildings or trees obtrude, a card, with arched edge laid over the sky portion of the negative, will suffice; but with a well-wooded landscape, "stopping-out" must be resorted to if the sky prints through. When painting around the edges of foliage, to avoid cutting lines, so suggestive of scissors, the hand should be kept in a tutored palsied motion, which causes the brush to describe a serrated movement. So treated, the black varnish will not impair the softness of the outlines. The foreground printed satisfactorily, the print is then removed to another frame, and placed in contact with the cloud negative, and the foreground masked with cardboard, arched at its outer edge as before advised. By a judicious moving and placing of the mask as the printing proceeds, atmosphere and distance are effectively rendered. Or clouds might be produced on either side, to compose with the picture, by blocking out the unneeded portions with the mask. In such case, the white parts are tinted when the print is finally removed from the frame. Printing-in clouds is the easiest form of combination printing; by no means is it the least effective.

A NEW METHOD OF WORKING WET PLATES WITHOUT TENT OR DARK ROOM.

BY B. J. EDWARDS.*

ONE of the greatest hindrances to the practice of photography among amateurs, and to the production of out-door pictures by professional photographers, has always been the necessity for the use of a dark tent or chamber to shield the plate from daylight during the operations of sensitizing and developing.

From the earliest days of photography attempts have been made to overcome this difficulty, or invent a light and portable substitute for the dark chamber which is ordinarily used by the operator at home. Mr. Scott Archer—who was a true inventor, and to whose fertile brain we are indebted, not only for the collodion process, but for most of the apparatus and appliances necessary for its daily practice—saw the necessity of devising some means of finishing the plate, or developing the picture before removing the camera; and, to this end, designed an arrangement by which the plate was manipulated inside the camera, the body of which formed a dark box which served for this purpose. This contrivance was, however, found very inconvenient in many respects, while it necessarily added very much to the weight of the apparatus employed in the field.

Since Mr. Archer's time, an infinite variety of dark tents and manipulating boxes have been invented, some of which are ingeniously constructed to serve the required purpose; but all are open to some objections fatal to their general utility.

The portable dark chambers hitherto made for use in the field are of two classes: first, those in which the plate only is protected from the light; and secondly, the tent in which the operator himself was partially or wholly enclosed. In the first place, the hands of the operator were passed into the interior of the box, through sleeves made of some dark material, while the progress of development was examined through a small pane of yellow glass in the top of the box, the interior being lighted by a large pane of yellow glass in the front of the box.

I worked for several years with a box of this description, but always felt great inconvenience arising from the difficulty of not seeing perfectly the progress of the operations going on inside the box, and from the fact that both hands were tied, as it were, to the box, and must not be removed for fear of injury to the plate. Besides, a dark chamber of this kind could only be used for very small plates. When larger sizes of photographs were required, it became necessary to devise a different form of dark chamber, which should allow of greater freedom in manipulating the plate.

In this second form of tent the operator is partially or wholly enveloped in the tent, which is made as much as possible to resemble the dark chamber or room ordinarily used for photographic purposes. An immense variety of tents of the latter kind have been designed and brought into use for out-door photography, and at the present time almost every landscape photographer has his own pet tent, fitted up to suit his fancy or convenience.* But, notwithstanding the great ingenuity brought to bear on the subject, and the degree of success which has attended efforts to overcome the minor difficulty of detail connected with the construction of portable dark tents, there has always remained this one serious objection, viz., the extra bulk and weight which are necessarily added to the apparatus employed in out-door photography. It is, as I believe, owing solely to this "weighty" objection to the employment of a dark tent, that dry processes have received so much attention, and that such strenuous efforts have been made to discover a dry process which shall possess all the good qualities of wet collodion. Without going into the much discussed question of "wet versus dry," I think I may venture to assert that this perfect dry process has not yet been discovered.

Good negatives have been made with many of the dry processes, but I think all who have had experience in both

wet and dry will agree with me, that there are many advantages in the wet process which dry plates do not possess; not the least amongst these I may mention, rapidity of exposure, development, and far greater certainty of result, without the extra trouble and risk in preparing and keeping the plates. The strongest argument in favour of dry plates has been their great portability; but once get rid of the extra impedimenta needed for the use of wet plates in the field, the only strong point in favour of dry plates falls to the ground. In fact, the reason for their use no longer exists. If further proof of this were needed, it may be found in the fact that in portraiture, and in all the higher branches of photography, the wet process is exclusively employed.

In the apparatus which will be shown to you this evening, this question of portability has been fully considered; the bulk and weight of the whole apparatus necessary for manipulating wet plates in the field being little more than that of a couple of the ordinary double backs used for dry plates.

In order that the invention should be of perfect utility, I may state that in designing this apparatus I considered the conditions of success to be, first, extreme portability; second, convenience in working; third, perfection of result; and I think I may fairly claim that this invention fulfils each of those conditions. I have also secured the minor advantage that the hands of the operator are not stained by the chemicals.

It is not necessary to give a detailed description of the complete apparatus, or the various possible modifications of the principle on which it is constructed. Full details will be found in the specification which I have filed at the Patent Office.

It is often extremely difficult to convey in a few words a clear idea of the simplest mechanical contrivance, without explanatory drawings or illustrations; I will, therefore, merely state that the various parts of the new apparatus will be found perfectly adapted to the purpose required; thus the method employed for sensitizing the plates I have found in practice to be superior and easier to work than the ordinary method of using an upright dipping bath. There is no liability to accidents, such as breaking of the dipper, or the falling off of the plate, while much less than the usual quantity of nitrate of silver solution is sufficient to do the work with far less risk of stains.

The same remarks will apply to the plan adopted for developing the plate. I am convinced that a few trials will prove that the operations both of sensitizing and developing are performed with greater ease and certainty than they can be by the ordinary method now employed in the most commodious dark room or tent.

It has been my aim to secure the best possible means for working the wet collodion process at home or abroad, with the additional advantage of enabling the operator at will to dispense with the necessity for a dark tent or room, and work in the open daylight without risk of injury to the negatives.

Before proceeding to show you the apparatus, and the mode of working, I beg leave to call your attention to a modification I have made in the iron developer, and which will be found of great advantage both for work in the studio and the field.

I have for many years been in the habit of using a saturated solution of iron for making the developer, but as it is well known that a solution of the ordinary proto-sulphate of iron rapidly becomes discoloured and unfit for use, I have made a compound solution, which, I find, will keep perfectly for an indefinite period. The formula for this compound solution has been recently published in the photographic papers, but as some present may not have noticed it, and as I consider it to be of great importance, I will repeat the formula, which is as follows:—

Common sulphate of iron ...	1 pound
Ammonia sulphate of iron ...	1 "
Sulphate of copper... ..	1 ounce
Water to make a saturated solution.	

* Read before the South London Photographic Society, April 13.

This solution will keep for any length of time, and with it a great variety of iron developers of any strength may be made at a moment's notice. To use it for out-door work, proceed as follows:—To one pint of water add one ounce of glacial acetic acid, and one ounce of alcohol; this I will call solution No. 1. In another bottle may be carried one or two ounces of the compound iron solution, called solution No. 2. When required to develop a plate, add a few drops of solution No. 2 to one ounce of No. 1 solution; about thirty drops of the former will make a capital developer for ordinary work (there is, however, great latitude in this respect). A developer suitable for a distant well-lighted view would be utterly useless for rendering the detail of a mass of dark foliage. Very much depends upon using a developer suitable to the subject.

After the details are well out (and I may here add that there is no fear of fogging the plate), pour away the developer, and rinse the plate with a small quantity, about one ounce of No. 1 solution, without the iron; this will effectually stop the development of the picture, which may then be exposed to sunlight without injury. No water is required for washing. The negative may be placed in a metal or varnished wood plate-box to be fixed and intensified at home at leisure.

The above method will be found very convenient when working wet plates in places where water is scarce, and will prove especially useful with the apparatus I am now about to show you.

The only chemicals it will be necessary to take into the field will be a bottle of each of the above solutions, and a bottle of collodion.

I will now proceed to take a negative with the graphogenic apparatus. I have used this name as a distinctive title, and one which is sufficiently descriptive to serve the purpose. I have reason to hope that this little contrivance will prove a boon to professional photographers, and be the means of awakening renewed interest among amateurs, many of whom, owing to the necessity of using a dark room or tent, have given up the practice of our fascinating art science.

ON THE PRODUCTION OF SMALL PORTRAIT NEGATIVES SUITABLE FOR ENLARGING.

BY EDWARD W. FOXLEE.*

DURING the last few years much has been written on the production of enlargements from small negatives; and the recent introduction of curved and concave plates for the purpose of taking the negatives upon has induced me to offer a few remarks upon the subject.

If we examine a life-size enlargement from a small negative, we are struck with its coarse and unpleasant appearance. In the case of a gentleman, the beard, instead of being the same thickness as in life, is generally represented as twice or cord, and what is so easily noticeable in the beard applies more or less to all parts of the picture. Why is this? The answer, I think, is—firstly, that part of it is caused by the astigmatism unavoidably introduced in flattening the field of the lens with which the negative is taken; secondly, by a slight movement of the sitter during exposure; and, thirdly, by the coarse deposit forming the image. We will now consider the remedies I propose for these defects.

First: the astigmatism. If we consent to use concave plates for our negatives we at once get rid of that, as the optician can give us a lens almost entirely free from it, and giving the most perfect definition possible to obtain, and, at the same time, of much shorter focus. It is well known that the great difficulty in constructing a lens to work rapidly on a flat plate has been the large amount of astigmatism present to secure flatness of field so as to render the lens useless, certainly for enlargements. I am now speaking of lenses of shorter focus than those generally termed carte-de-

visite. I think it is quite possible for the optician to give us a lens that will work in one-fourth the time now required for our ordinary rapid carte lens; and, if the same lens be used for enlarging, any little distortion in the original negative will be corrected by the enlargement. Of course, theoretically, this will only apply where the enlargement is life size, but I think it will, also, practically, to all sizes.

This is a question for the optician, which I do not profess to be. If, however, I am right in my surmise, this will help us over our first, and partly over our second, difficulty, by shortening the time of sitting.

Now for the third: the coarseness of the deposit. The negatives generally recommended for enlargement are those termed "over-exposed positives," developed with iron or bromo-iodized collodion. This, I think, is a mistake; for if we put such a negative under the microscope, we find the image formed of particles of silver far too large to represent the hair and fine details in their proper proportion in a picture (say) of three quarter inch face. It is quite possible to produce a negative suited to our purpose—without prolonging the exposure—in which the image consists practically of a stain instead of a deposit, if we go back to the old pyro development on simply iodized, not bromo-iodized, collodion, which for the best results I certainly recommend; but it must be used under its most favourable conditions.

I will now describe, for the benefit of those who may not be familiar with it, that now almost obsolete process. The collodion must, of course, be quite structureless. I know of no better formula than that given by Mr. Hardwich in the sixth edition of his "Photographic Chemistry." For the pyroxyline—

Sulphuric acid, s.g. 1.845 ..	9 fluid ounces
Nitric acid, s.g. 1.457 ...	3 "
Water	2 $\frac{3}{4}$ "
Cotton	150 grains

Immerse for ten minutes, at a temperature of 150°. I have always found I have got on better by using two drachms less water than that recommended by him.

For the collodion—

Pure sulphuric ether (hot methylated), s.g.	
.725	4 ozs.
Alcohol	s.g. .805 2 "
Pyroxyline	45 grs.

For the iodizer—

Alcohol, s.g. .825	2 ounces
Iodide of potassium	26 grains

Two drachms to be added to each six drachms of plain collodion. The collodion and iodizer—and these should be prepared and allowed to settle, and iodized only a few hours before use, as its sensitiveness, unlike the bromo-iodized, becomes rapidly less. The ether used should be tested for acidity, as that is fatal to its keeping properties and sensitiveness. If the methylated ether be substituted for the pure, it should be that known as "washed and re-drawn," in which case I recommend the iodide of ammonium instead of the potassium salt for the iodizer.

The bath should consist of thirty grains of nitrate of silver to the ounce, and be saturated with iodide. The way I always prepared mine was to dissolve twenty drachms fused nitrate of silver in four ounces of distilled water; then add about eight grains of iodide of potassium dissolved in one ounce of water, stirring until dissolved; and then test with litmus paper for acid; but this will rarely be found if the fused nitrate be used. But if the crystallized be used, it should be the pure re-crystallized, which may be slightly acid, in which case neutralize with moist oxide of silver. Add thirty-five ounces water, and filter. The bath must be kept quite neutral if the highest amount of sensitiveness be required. If, on trying a plate, it should slightly fog, one drop of glacial acetic acid to the pint will correct it, supposing it to have been made of pure materials.

* Read at a meeting of the South London Photographic Society, April 13.

Nitric acid should on no account be added, as it tends to give a crystalline image, and destroys the extreme sensitiveness.

The exposure in the camera should be the same, or rather less, than for an ordinary negative with iron developer.

The developer I use contains two grains of pyrogallic acid and fifteen minims of glacial acetic acid to the ounce of water, with sufficient alcohol to make it flow easily. It should be used new, as when old it is not so energetic, and has a tendency to bronze the shadows. With this developer the image will appear rather rapidly, of a pink colour; and care must be taken not to over-develop the picture, as the colour obstructs more light than it appears to do at first sight.

It should be fixed with a very weak solution of cyanide of potassium, which will not remove the iodide of silver in less than from forty-five seconds to a minute, or it may injure some of the delicate half tones.

I had intended to have shown some examples of the fineness of the deposit produced by different developers and iodizers, but press of other matters has prevented me doing this. I have, however, brought down a few old negatives taken some years back by the means I have described, and you will see the image is composed of a pale elaret-colour stain. They are, of course, much too intense for enlarging, but of the character I advise for the purpose.

THE AUTOTYPE PROCESS.

BY TOM TAYLOR.*

But the Autotype proper has been more nobly employed on examples which eminently deserve the title of "school copies," too, though fitted for higher schools and older scholars. We refer to the complete reproduction, by the indefatigable A. Braun, of the mighty frescoes of Michael Angelo in the Sistine Chapel, and those of Raphael and his scholars in the *Stanze* and *Loggie* of the Vatican. Two articles in the *Portfolio*† have already been devoted to these two noble series, but we cannot forbear from going back to them here, in order to insist on the essential superiority of these autotypes to all that engraving has done, or can do, in bringing home to the mind the beauty of Raphael and the majesty of Michael Angelo. Of such work, for example, as the "Disputa del Sacramento," or the Prophets and Sibyls of the Sistine ceiling, and still more, perhaps, the naked youths who support the roundels above them, these autotypes give us an altogether new impression. In the range of Prophets and Apostles who flank the Divine Son and his Virgin Mother in the "Disputa," as in the Angels who float around the Father, these autotypes reveal to us heights and depths of grandeur and dignity, of grace and loveliness, of sublime and pathetic expression, of which the best engravings of the subject convey but a faint and feeble suggestion. This holds true also of the School of Athens, the *Incendio del Borgo* and the *Miracle of Bolsena*. They also enable us to appreciate, as engraving never did, the enormous distance that separates the work of the master from that of his pupils, whether in compositions or single allegorical figures. Only in a few of the latter, from the hand of Giulio Romano (as emphatically in the Justice of the latter), we see an occasional approximation in this one scholar to the height of the teacher. They show, moreover, only too honestly, the ravages of time and damp, completed by the worst ravage of restoration. These together have robbed the Bible pictures of the *Loggie*, in particular, of all traces of the master's hand, except as regards the composition and general character of the groups. It must be owned that the Autotype is as pitiless in its discovery of retouching

and restoration, as it is potent in bringing out the essential beauties of great originals.

But intensely interesting for their manifestation of new power, expression, and grace, as are the autotypes of the *Stanze* frescoes, it is for their revelation of the unequalled grandeur of the genius of Michael Angelo, as embodied in the Sistine frescoes, that all lovers of the noblest art should be most grateful to the autotype process. Now, for the first time, those who have never been at Rome can understand the supremacy in art awarded to Michael Angelo by the concurrent judgment of the severest and most skilled critics. Those who have already, in the Sistine itself, learnt to bow down before the majesty of that mind as displayed in its master-work, will here find an opportunity of studying those colossal conceptions, figure by figure, group by group, with a patience and minuteness impossible in the chapel itself, from the conditions under which the originals must be viewed there. How these extraordinary reproductions were taken, by what wonderful contrivances of scaffolding, what happy accidents of light, what patience, what dexterity of manipulation, we cannot imagine. Suffice it to say, that the achievement has been consummated with a success nothing short of triumphant. A framed autotype of the whole ceiling is now brought within reach of even modest purses, though the complete series of the Sistine, embracing not only all the details of Michael Angelo's work on a large scale, but all the works of the older painters which he allowed to remain—Perugino, Sandro Botticelli, Luca Signorelli, and Cosimo Rosselli—as we learn from Mr. Scott's article, is necessarily costly. The "Last Judgment" all but defies autotypic reproduction. But the other designs on walls and roof—above all, the nude figures of youths, which merely fill up the space over the Prophets and Sibyls, and claim no specific names or characters of their own—come out with a strange and surpassing power, such as belongs to no other painted work in the world.* One can understand, after seeing these, how it was that Reynolds, himself a true man of genius, however different his time and path in art from those of the great Florentine, should have desired, in the evening of his laborious life, and in the memorable close of his concluding discourse, that the last words which he should pronounce in the Academy, and from his Presidential place, should be the name of Michael Angelo. Not less worthy of note, and more intelligible than ever after looking at these autotypes, is the passage which immediately precedes that harmonious close:—

"If the high esteem and veneration in which Michael Angelo has been held by all nations and in all ages should be put to the account of prejudice, it must still be granted that those prejudices could not have been entertained without a cause. The ground of our prejudice, then, becomes the source of our admiration. But, from whatever it proceeds, or whatever it is called, it will not, I hope, be thought presumptuous in me to appear in the train, I cannot say of his imitators, but of his admirers. I have taken another course—one more suited to my abilities, and to the taste of the times in which I live. Yet, however unequal I feel myself to that attempt, were I now to begin the world again I would tread in the steps of that great master; to kiss the hem of his garment, to catch the slightest of his perfections, would be glory and distinction enough for an ambitious man."

Students cannot better prepare themselves for reading what Sir Joshua has written of Michael Angelo than by studying these autotypes. Of course, they will soon be found in the library of every leading art-school.

(To be continued.)

* These autotypes are the more valuable because the ceiling, extensively cracked in 1797 by an explosion of gunpowder in the Castle of St. Angelo, is yearly becoming more liable to disintegration. The decay, which has already erased some of the figures, will no doubt gradually spread; so that the whole ceiling must in time become little better than a grand wreck. How precious will then be such a record of its glories as these autotypes will have preserved.

* Continued from p. 174.

† By Mr. W. B. Scott, Nos. 13 and 14.

GERMAN CORRESPONDENCE.

PECULIARITIES OF LOESCHER AND PETSCH'S STEREOES—A NEW WAY OF MAKING STEREOES WITH A SINGLE OBJECTIVE—ON THE TIME OF FLOATING POSITIVE PAPER—THE VICTORIA CARD—A DEVELOPER WITHOUT ACETIC ACID—MEDALLION

In the "Sphynx" of the January number of your Journal, some one asks the question how it happens that in the stereos by Loescher and Petsch, "Gems of German Life," the figures on the two halves of the picture are not of equal size, and how it is possible that, nevertheless, the stereoscopic effect is so splendid. I answer the first question by stating that Loescher and Petsch employ lenses of *unequal focal lengths*. The focus of the one objective is a little longer than that of the other. The second question is explained by the faculty of the eye to accommodate itself to circumstances, for it has the power to combine in the stereoscope not only pictures of unequal size, but also those which are generally different, provided this difference is not too excessive. I have two pictures of the same person, which were taken one after the other; the position is not exactly alike, and still they readily combine in the stereoscope.

Another original question which, however, was not proposed in your "Sphynx," but in the German Photographic Society in New York, is as follows:—How is it possible to make a stereoscopic picture with a single objective and without moving the camera? The gentleman who put the question gave the answer also. He said we take a seven or eight-inch objective, and use a stop with two openings instead of one. The possibility was doubted generally, still it is possible, although not in the manner described above. I will try to explain.

In the April number of last year, on page 131, I wrote to you "On the Effect of Large Apertures," and remarked that in a lens of 2½-inches diameter, the diametrically opposite points are already as far removed from one another as the eyes in our head, and as our right eye sees a little more of the right side and our left eye more of the left side of a sitter, so also does the right and left side of a lens take in more on either side, and hence produces an almost stereoscopic picture on the ground glass.

This really stereoscopic effect which is produced on the ground glass when working with large lenses, must certainly have been noticed by nearly all the practical photographers. How a stereoscopic picture can be made with a single objective, and without moving the instrument, explains itself very easily. We take a four-inch lens of as short a focus as possible, and cover, with a piece of pasteboard, all but one inch of the left side of the objective; we now take a picture; we next cover, all but one inch of the right side of the lens, and again take a picture. Such pictures, together, will give a stereoscopic effect, which will be more perfect in proportion as the distance between the object and the lens is shortened.

With a three-inch lens which I covered all but half an inch, I have succeeded in making beautiful stereos of small models of machinery; but a diaphragm with two openings will not answer, as the pictures on the ground glass will cover each other.

In our Society for the Promotion of Photography, Mr. Prüm gave lately some interesting facts of the influence which long-continued "floating" exercises on the positive paper.

A manufacturer sent him a quire of arrowroot paper with the direction to float it on the silver bath for three minutes. The results were very indifferent: the pictures looked gray and weak, and appeared to be more inside the paper than on its surface. Mr. Prüm tried next what effect it would have if the time of "floating" was shortened. A piece of paper was placed on the bath for only about half a minute, and the result was really surprising: the pictures left nothing to be desired—were vigorous and full of beauty. Their beauty was still heightened when they, immediately

after sensitizing, were dried with blotting-paper. He obtained pictures the strength of which was equal to albumen prints.

The above goes to show that it is not always well to follow the directions of the manufacturers. We in Europe generally float too long. I was surprised to learn from Mr. Moore, in Philadelphia, that he floats the Dresden albumen paper for only three-quarters of a minute, while we are in the habit of floating it for three minutes. I myself afterwards tried short floating, and found the pictures much more brilliant than before.

The Victoria card gets more and more popular. Grasshoff pushes this new size very much. He has adopted a very simple manner of gaining customers for it: when a person orders a dozen cartes-de-visite, he prints also, from the same negative, two or three Victorias, and shows them to the party. Generally the Victorias are taken, and, in most cases, the preference is given to them over the cards.

The proprietor of a large establishment in which "reproductions" are principally made, complained to me recently that he had to spend such large amounts of money for glacial acetic acid for the developer. I advised him to discard the acetic acid, and this works really very well. The expensive glacial acetic acid can be left out of the developer entirely, and the pictures have even greater intensity. It is only necessary that some alcohol should be present in the developer in order to make it flow more readily; common alcohol, containing fusil oil, will answer for this purpose. When the developer is to be kept for some time, it is advisable to add a small quantity of another acid; for instance, the cheap sulphuric acid. Such a developer is made as follows:—

Sulphate of iron	60 parts
Sulphuric acid	3 "
Water	1200 "
Common alcohol	36 "

Yours very truly,
DR. H. VOGEL, in the *Philadelphia Photographer*.

Correspondence.

CHILDREN IN THE STUDIO.

SIR,—So long as photographers content to lower themselves to the ideas of their customers, instead of raising themselves and their customers to definite artistic principles, so long, I suppose, will such difficulties be possible as those described in a paper you published last week on "Children in the Studio."

It seems rather hard, and possibly unjust, to toil a man who has apparently spent about a couple of hours in unavailing attempts to photograph a troublesome child, that he might have avoided much of the trouble, and most likely have accomplished all he desired in a brief quarter of an hour, if he had used a little more tact and *savoir faire*; and yet, on a careful perusal of the paper alluded to, there is, to me, somewhat of a temptation to come to this conclusion. Ho will, perhaps, pardon a few suggestions.

His very first act was, it seems to me, a mistake. He begins by asking the old lady who has come along with her married daughter, "How would you like the baby taken?" Now, fancy Millais or Grant sitting down to his easel, and enquiring of his sitter, with an uncertain air, "Pray what sort of a portrait would you like?" Is it not as much as to say, "I really don't know what I am going to do; what would you do under the circumstances?" We can all of us see the absurdity of such an idea at once. It ought to be just as absurd in a photographer. Given a certain kind of picture—carte, cabinet, Victoria, or whatever it may be—this is your customer's affair; the rest is yours; and no man in a studio is equal to his position who cannot, with ready firmness, combined with insinuating suavity, insist upon having his own way when he knows he is right. This is the more necessary with children, because the conditions ensuring successful portraiture are narrowed to a very limited range. For instance, in the case before us, Philip Henry is to be photographed standing when he can't

stand, and flogging a horse into the bargain. What is to be done? I should very quietly say, as I have had to say to such ignorant people hundreds of times, "I have no objection to take your interesting little child in a position which I believe to be impossible, when I have first taken a portrait of him in a position which I know to be possible." There is no occasion to say this offensively. Be conciliatory, be courteous; but when you see an impossibility or an absurdity ahead (and you ought to be able to see one at once), be resolute in avoiding it.

Another mistake is, the presence of the mother and daughter in the scene at all. I never allow it; or, at any rate, if the child is afraid of strangers, and requires the parental presence as a sympathetic link, I never allow them to interpose with the picture. Let the parents amuse the child as much as they like before and after the exposure, but let the amusement of the interval of exposure be from your own resources alone.

Another delusion consists in the too prevalent idea that the portraits of children must be instantaneous: just a hasty snatch at the cap, a wild unearthly yell (to attract attention), and then the dark room and a half-exposed picture. As a proof of the fallacy of this notion, I send you herewith a few cartes of children, not one of which was exposed less than five seconds, and many of them seven or eight; and yet I think you will agree with me that in none of them is there any perceptible motion, nor anything unfavourable in the expression.

The great secret of success in children's portraits is not instantaneous exposure, but in the concentrated attention of the child on *yourself* as you coax its picture through the lens on to the plate.

And now I can give your contributor an idea. Philip Henry had to be taken on his grandmother's knee after all. *Query*—How to get rid of grandmother? In one or two of the cartes sent you will see how this very desirable consummation is effected: simply by throwing a black lace shawl over her. In the resulting picture the child is apparently leaning against a sofa or arm-chair, or in front of an ordinary background. Nobody would dream that grandmother was the better.

It might, perhaps, be objected, that the kind of treatment I uphold of customers in the studio, and especially of mothers with their children, might tend to drive them away altogether. I can only say, so far as I am concerned, it has never been so. People will respect you when they find you respect yourself. Indeed, the best commentary on the opposite course is found in the text of the paper I have been criticising, where, after endless bother and vexation, the photographer was rewarded with the munificent sum of *three shillings!*—I remain, yours very truly,
LUX ET PRÆTEREA NIHIL.

PHOTOGRAPHY AT THE INTERNATIONAL EXHIBITION.

SIR,—Permit me to say a few explanatory words on this subject, for it appears to me, from the correspondence which has lately taken place in your journal, that great misconception exists as to the nature of the Exhibition. In the first place, the Exhibition is of "selected objects" in all the classes, and differs, therefore, essentially from all other exhibitions that have hitherto taken place. Secondly, no medals or prizes of any kind are awarded; the admission to the Exhibition becomes the equivalent of a medal. The objects sent in are examined by a committee of selection, and those only retained for exhibition which are deemed worthy of a place. It is, in fact, applying to the Exhibition of Art and Manufactures the principles of the Royal Academy as regards the pictures annually sent for hanging. Excellence, novelty of production, and space necessarily rule the selection. How far the committee of selection are competent for the work, of course disappointed exhibitors must be at liberty to hold their own opinions; but the public will have an opportunity of forming theirs. Hanging committees always have been, and, I suppose, to the end of time, must expect to be, a target for abuse of all kinds. Ignorance, incapacity, and interested motives of the lowest kind are freely attributed to them by the vulgar, who seem to think that gentlemen who undertake gratuitously a laborious and thankless office at once lay aside every attribute which entitles them to hold their position in society as men of honour and justice.

I am glad to see that Messrs. Robinson and Cherrill gracefully admit their error on becoming acquainted with the true state of the case as regard their pictures. I felt sure, as soon as I read their letter of complaint, that the committee of selection

had most properly rejected the pictures named by them in their letter, simply on the ground of want of novelty, even if space had not inexorably forbidden their display. Their merits few would venture to dispute. Again, when my excellent friend, Mr. Hubbard, told us that his exquisite little gem "Stolen Moments," or "Pensive Thoughts,"—I forget which—had been rejected, I saw at once it had been rightly so treated. It was not new; it had been seen and admired in public exhibitions previously. I regret that it cannot appear side by side with the foreigner, to show what an Englishman can produce. I hope that Mr. Hubbard has sent some new work of that class, for there is no one so capable as he of maintaining the position of England in that special walk of the art. Space and novelty, too, must be borne in mind by my friend Mr. Blanchard, when he complains of the rejection of some of his pictures. Those named in his letter have all been exhibited before. Their rejection is no slur on his merits. They are too well known to admit of doubt. In his own special walk, Mr. Blanchard stands in the highest rank, and I doubt not that what the committee of selection have retained will fully sustain his reputation. It is a well-known fact that artists rarely, if ever, are the best judges of which are their most meritorious works. I have specially used the term "friend" to both Mr. Hubbard and Mr. Blanchard, first, because I am proud to be able to do so, and next to show that, however much friendship might incline me to show favour, my verdict on the present occasion is against them on their own showing.

I fear, from reading the various letters which have appeared, and from information the legendary "little bird" has brought me, that photographers have, in many instances, thought more of quantity than quality, and have endeavoured to utilize the Exhibition as an advertising medium rather than as a display of fine art, forgetful that they are artists, and not advertising traders in quack medicines. Photography takes its place in this Exhibition among the fine arts. Let us try and deserve the title.

In making the foregoing remarks, I beg leave to say that I am in no way connected with the management of the Exhibition.—I am, &c.,
P. LE NEVE FOSTER.

PS.—I think it would be well if, at the Society's exhibition, some restriction could be adopted to stop this growing evil; say by limiting the number of pictures any exhibitor may send, and sternly rejecting advertising show-boards.

SIR,—We must all feel glad that Mr. H. P. Robinson has written the letter he has in the last NEWS. The original attack made upon the Committee appeared very unfair, and it is gratifying now to see it was made under false ideas.

Your correspondent, "Truth before Favour," asks about an "Old Stager." It is rumoured, and his letter bears it out, that one portraitist sent in the picture that always stands at the door of his rooms in Piccadilly, which was very properly rejected, as the element of novelty should surely have some consideration in selecting for an exhibition.

Your correspondent is also right in his remarks as to Dr. G. C. Wallich, who, if imputation of motives were permissible, possibly might be supposed to remember a communication in the *Athenæum*, by one of the gentlemen of the Photographic Committee, pointing out the scientific errors or folly of one of his proposals. Hence, possibly, his going out of his way to attack the Committee, he having, however, not sent anything in, and having, therefore, no *locus standi*.—Yours truly,
London, April 17th.
M. R.

SIR,—In the letter of Messrs. Robinson and Cherrill, in which they, in what seems to be a spirit of fair play, withdraw any suggested imputations on the Photographic Committee at the International Exhibition, they refer to information they have received, and to explanations with which you are personally familiar, as satisfying them that the Committee in question was actuated only by a regard for the interests of the art in making their selections and rejections. Whilst it does not seem at all difficult to believe, on general grounds, that this should be so, as specific explanations are referred to as existing, is it not due to photographers generally that you, in your discretion, should make known to them details which may probably interest and satisfy them as much as it has done Messrs. Robinson and Cherrill?—Yours,
W. E.

KEEPING QUALITIES OF DRY PLATES.

DEAR SIR,—Having seen many queries as to the keeping properties of various dry plates, I venture to give you my experience in the matter.

I have found coffee plates keep well and tolerably sensitive. For instance, on the 31st March I exposed a plate which I prepared in May last year, thirty seconds, with a pair of Dallmeyer's rapid landscape lenses, second size, rotating stop, in sunlight, and obtained a fair negative. I developed as follows:—First, a wash of plain solution of carbonate of ammonia; then plain pyro and ammonia, till all details were well out; and intensified with ordinary citro silver and pyro.

A tea-plate prepared in October last was exposed the same day, and for the same time, with the same development, and also gave a good negative.

I have tried coffee and gum, and like the plates much. I find them quite as sensitive as the ordinary collodio-bromide plates. They are a little more trouble to prepare, as are all plates where the silver bath is used; but one is not tied down to a certain kind of pyroxyline or collodion and bath, which is an advantage to amateurs who, like myself, live in a place where the necessary materials for the collodio-bromide processes are not readily procured.

The keeping qualities of the coffee and gum plates I have not, of course, yet tried; but I see no reason why they should not keep their sensitiveness quite as well for long periods as plain coffee.—I am, sir, yours faithfully, JOHN B. C. FOX.

Lutterworth, April 18th.

ALBUMS FOR NEW STYLES.

SIR,—In last week's PHOTOGRAPHIC NEWS we notice two letters respecting albums for the Victoria cards. The writer who signs himself "Middlesex" seems to imagine that they are not obtainable. We here beg to assure him that we shall be able to supply them to him, or to any others, and at the reasonable price of 7s. each. We must, however, at the present, ask a little indulgence as to time for the execution of an order. Mr. F. A. Bridges, in his letter, suggested a special album for the portraits of deceased friends. We have pleasure in informing him such an album has been made by us six months ago, and is now kept regularly in stock.

We wish to make a little observation for the benefit of those gentlemen who declaim against the want of energy on the part of dealers and manufacturers, in introducing and making articles suitable for novelties. The fact is, it is so much the interest of the dealer to introduce novelties, that if he were not checked by the evil consequences of failure, a loss to himself and to his customers, we should see novelties out every week, and pushed by the various houses of business, till photographers would be sick at the sight of anything new.

With regard to the Victoria card, in our opinion, it is a size that approaches too close both to the cabinet and carte-do-visite; consequently there will be, in reality, no extra business from it; any orders received will be so much from the carte or cabinet; we, therefore, determined to hold back and wait. By this we mean, we would wait for the demand, and not seek to create it. We shall, of course, be most happy to execute any orders we may be favoured with, both for the Victoria cards or albums.

The cameo-vignette portraits will show that we are quite ready to introduce and make known a novelty. This style, according to our judgment, will prove a great success, and, consequently, give a large increase of business to photographers, as well as to the man of business.—Yours truly,

Soho Square, London, April 19th. MARION AND CO.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE ordinary monthly meeting was held at the Memorial Hall, on Thursday evening, the 13th inst., Mr. NOTON, V.P., in the chair.

After the routine business had concluded,

Mr. WARBURTON exhibited a pair of Mr. Edwards's combination printing-frames, which attracted much attention.

A long talk followed on albumen, and the various modes of its employment in photographic practice. Nothing new was elicited.

The subject of summer out-door meetings came up for con-

sideration, and met with a very discouraging reception. It was ultimately decided to leave members to arrange photographic trips among themselves.

THE CHAIRMAN made some remarks on the albumen process on glass, commending it for the beauty of the results obtained by it, and promised to read a paper on the subject at the next monthly meeting.

THE meeting, which was only moderately attended, was then adjourned.

C. ADIN, Hon. Secretary.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held in the City of London College on the evening of Thursday, the 13th inst., Mr. SEBASTIAN DAVIS in the chair.

THE minutes of a previous meeting having been read and confirmed,

MR. B. J. EDWARDS read a paper on working the wet collodion process without a dark room or tent (see p. 186). After reading the paper, Mr. Edwards exhibited his new "Graphogenic" apparatus for working wet plates in daylight; and, in the course of the evening, showed its working by producing a negative with the aid of the magnesium light, Mr. Solomon's lamp, under the charge of Mr. Walter Paul, being employed.

After some conversation,

MR. FOXLEE asked Mr. Edwards what part was played by the sulphate of copper in the developing solution he used.

MR. EDWARDS found it checked the tendency to ready oxidation of the iron solution, and was, therefore, of great value in a concentrated solution to be kept ready for use.

MR. HENDERSON had found that camphor had a similar action.

MR. EDWARDS said that as camphor was very sparingly soluble in water, it would scarcely be available in the stock concentrated solution. He found the plan of using a concentrated solution, diluting it as required, very valuable. Sometimes he used the solution with scarcely any dilution, and had, in such cases, obtained a negative of a baby with half a second's exposure.

MR. FOXLEE had found that a silver solution kept in a bath lined with pure india-rubber was spoiled in a few weeks.

MR. EDWARDS said the solution need never be kept in his bath more than a few hours; and, owing to the small quantity necessary for covering the plate, fresh solution was constantly required. He had known pure india-rubber become much contaminated with sulphur by lying in contact with vulcanized india-rubber in a warehouse.

MR. WHARTON SIMPSON had used an india-rubber lined bath for some years for landscape work without inconvenience, but the solution was always removed from the bath at the end of the day's work.

MR. HOWARD had used india-rubber constantly for the watertight top of his bath without injury.

After some further conversation on the facility for watching development through the two non-actinic glasses, on the shellac varnish for lining the silver bath, and a vote of thanks proposed in some eulogistic remarks from the Chairman, the subject dropped.

MR. FOXLEE then read a paper on small negatives for enlargements (see p. 187), and exhibited some negatives.

After some conversation on the superiority of pyrogallic acid for giving negatives in which the texture is amorphous, and free from texture, deriving its non-actinic character from its colour rather than thickness of deposit, and a vote of thanks, the subject dropped.

THE CHAIRMAN reminded the meeting that the May meeting would be devoted to the exhibition of photographs, which members were invited to contribute, and to conversation thereon.

The proceedings then terminated.

Talk in the Studio.

ART PHOTOGRAPHS FROM COMBINED NEGATIVES.—We have recently been favoured by Mr. Adam Diston, of Leven, Fifeshire, with some further examples of *genre* photography printed from combined negatives, the plan of combining the negatives being that of Mr. Johnstone, of Wick. One is entitled, "The Smithy," and is an admirable rendering of the familiar interior of village smithy, with its forge, anvil, and medley collection of all kinds of implements and fragments of implements in irons, tongs, chains, horse shoes, and similar matters. The

smith himself, an elderly man in spectacles, has just lifted a piece of incandescent iron from the fire, and placed it on the anvil, the whole arrangement being singularly true to nature, and the composition fine as a work of art. "An Old Book Stall" is not less excellent. The open front of an old book shop is represented, with all kinds of odd volumes piled on the shelves in front. The proprietor, a venerable old man, with white beard, a perfect type of an old book-worm himself, is arranging some of the books, whilst in the dim interior an old woman is seen attending to some domestic duty. All is well composed, and in satisfactory relation: the white posting bills and prints which are hung about are carefully subdued in tone, so everything is duly subordinated to the fine head of the old man. Both pictures are well composed, quiet, and harmonious, and each is a capital rendering of a good thought.

GUM-GALLIC PLATES.—Mr. W. Brooks has handed us a print from a recently exposed gum-gallic plate, for the purpose of illustrating that reflection from the back of the glass, at times called "blurring," is not a necessary characteristic of these plates. The plate in question had no backing of any kind. The subject is a most trying one; the sun is nearly directly in front of the lens, a dark mass of ever-green foliage cuts against the sky, and right in front of the foliage is a delicate white marble cross. All the veins of the marble, and its polished texture and black lettering, are perfectly rendered, other portions being satisfactorily made out, and no trace of "blurring" manifest. The delicacy and softness of the picture are fully equal to the qualities of a wet plate negative. In a note on the subject, Mr. Brooks remarks:—"I find by my note-book that the photograph of the little marble tomb that I gave you last Thursday evening was taken with a Dallmeyer's No. 1 triplet, $\frac{1}{2}$ inch stop, and $1\frac{1}{2}$ minutes exposure, with the sun, as you will observe, in front of the camera. The cross is of polished marble. It was taken on a gum gallic plate, and I think you will agree with me, that if taken with a wet plate, the marble could not have been more delicately rendered. It was developed with iron, containing a small quantity of gelatine, about half a grain to the ounce. I hope by the end of the season to be able to give you a little information respecting dry plate work. In my hands my efforts have, I may say, nearly always been successful, and I think most failures occur from defective manipulation. With the morphia process, I, the year before last, prepared twelve plates very carefully, and had twelve good negatives equal to wet plates. I think you could not have a better specimen than the card as regards contrast without "blurring," which sometimes makes its appearance in dry plates."

THE SOLAR CAMERA.—Mr. D. A. Woodward has obtained, in the United States, an extension of his solar camera patent for seven years. In this country it was suffered to lapse some years ago.

SCROLL PORTRAITS.—Mr. A. Reeves sends us another of his scroll portraits, in which the shading of the partially rolled up scroll is produced by the action of light, without touching with the pencil, and is very effective.

WHERE TO GO WITH THE CAMERA.—Mr. E. Ward favours our readers with a hint as to where to go with the camera:—"Last September I took my first photographic trip. I went from London to Rugby, Leamington, Warwick, Stratford-on-Avon, Kenilworth, Leicester; these places all lie together, and scarcely a more interesting route could be found within easy distance. I had a fortnight out, and had I been very industrious, could have spent nearly all the time photographing. I took with me a portable camera, for $7\frac{1}{2}$ by 5 plates, a folding stand, and an ordinary plate box with Liverpool plates, all of which packed in a portmanteau with the rest of my luggage. The Liverpool plates were all that I could wish, they were not developed until I returned. I gave two minutes to each view, with a small stop, without having a failure. They are certainly a great boon to travellers who like to have some little token of their past journeyings, and who have not time to prepare their own plates. I think there need be no anxiety as to results if they only be kept from light, and the directions for developing followed." Our old correspondent, "A Practical Man," also proposes making some suggestions to tourists.

EDWARDS v. STUART WORTLEY.—This case, in which the plaintiff complains of infringement of patent in combination printing frames, is to come before Vice-Chancellor Malins. It has appeared on the cause list several times, but the hearing has been postponed. It will probably be heard at about the end of this week.

To Correspondents.

- DIE.**—The use of the word convex is an error; it should be concave. The die is concave, and the cushion or counter-die convex. 2. The proportions of the oval is somewhat a matter of taste; we described the size of those before us, which were effective and satisfactory. 3. The cards should be sufficiently stout to permit the convexity to be retained after the card has passed through the press; but cards of good ordinary quality and thickness will serve. 4. Albums for cameo cards should have recessed mounts to protect the convexity. 5. We do not know of any firm but Marion and Co. who have undertaken to supply the requisites for producing this class of work. 6. In the Victoria cards we have seen both busts and three-quarter length figures. The exact proportion is a matter of taste.
- J. T. (Fife).**—If you send a couple of shillings to our Publishers, we have no doubt that they will select you a specimen; or, probably, any London dealer will do the same. Portraitists rarely sell specimens except of published portraits, and many portraitists do not publish. No. 4 of the cards you send is best; the others lack modelling somewhat. From what you state of the image appearing slowly after long exposure, we should judge that you have either insufficient light, or that your chemicals are not in good order. Collodion and bath being in good condition, exposure sufficiently long, and the developer newly mixed, the image ought to appear quickly. The minute air-bubbles are doubtless the chief cause of small yellow spots.
- INGENIO.**—Much depends on the fineness of the day and the amount of light admitted into the building in which the public meeting is held. Under favourable circumstances as to light, a quick portrait lens, and chemicals in good condition, will doubtless enable you to secure a negative of a public meeting.
- T. S. (Guernsey).**—We do not know the address of the gentleman in question. Possibly the firm you mention can tell you.
- A. D. O.**—It is difficult, without further details, to say what is your cause of failure. It may be that your collodion is old and insensitive; it may be that the silver bath is out of order; it may be that you do not give sufficient exposure; it may be that your developing solution is old and oxidized. Any of these causes would give you the thin, poor image of which you complain. Sunning or boiling down is a good plan to rectify the negative bath. The dark colour of your printing bath may be removed by kaolin, or by adding a few drops of a strong solution of common salt, shaking in the bottle, and then filtering. Should you require to ask further advice, enclose some examples of your failures, from which we can judge better often than from description merely.
- D. D. (Belgian Subscriber).**—The removal of nitrate of ammonia from a silver bath without reducing the silver is a troublesome process. The simplest method is to precipitate the silver as a carbonate by means of carbonate of soda; wash well the precipitate, to get rid of nitrate of ammonia and nitrate of soda; then redissolve by means of nitric acid.
- KELSO.**—We have met with cases in which the rents appeared, at first sight, to belong to the collodion film, only the varnish appearing unimpaired; but, on a more careful examination, the rents were found to exist both in varnish and collodion. Are you sure this is not the case in your negatives? Have you tried the application of powdered charcoal—directed? This is a test as well as a remedy.
- J. W. L. K.**—Paper is the cheapest material upon which you can take locket pictures. Possibly it might be cheaper still to take collodion positives on mica or enamelled paper.
- F. B. M.**—You will find an article on the subject in another page. We are uncertain of the exact price. You will find details in an advertisement.
- D. L.**—The grey tone and lack of vigour in your transferred print are partly due to the condition of the chemicals, and partly to the use of an iron developer. A pyro developer will give you more vigour, and a warmer colour. A comparatively new and neutral nitrate bath, full exposure, and good light are necessary conditions of success.
- J. HUBBARD,** referring to his letter on the photographs at the International Exhibition, observes that he wrote because photographers had been invited to make known what pictures had been rejected, and he, whilst wishing to express no ill feeling, has no apology or retraction to offer. His "Stolen Moments" was generally admitted to be his best picture, and was rejected, and hence he had ground, he thinks, for surprise and disappointment. It must not be forgotten, however, that the fact that "Stolen Moments" had been much exhibited, and much noticed, deprived it essentially of novelty, and as the Committee were desirous of securing as much freshness of effect as possible, and as the excellence of "Stolen Moments" had made it more familiar to the public during the last year and a-half than the other, even older, pictures, they were retained, and it was rejected. Mr. Hubbard is admirably hung, and presents a respectable figure at the Exhibition.
- J. H. WOOLLEY.**—Thanks; in our next.

Several Correspondents in our next.

PHOTOGRAPHY AND TAXATION.

THE recent budget, with its objectionable proposal to impose a tax upon matches, has revived the suggestion, hitherto generally made in jest, to add to the revenue by means of a tax upon photographic portraits. On the occasion when the Chancellor of the Exchequer laid his proposals before the House, Mr. Crawford observed that as the right hon. gentleman had crossed the Atlantic to find a tax on matches, he should have borrowed another American notion and imposed a tax upon photographs, which would have proved a source of considerable revenue. In letters to the daily press, and in general conversation in political circles, the proposition has been repeated. One sapient gentleman, writing to a daily contemporary, says: "Why did not Mr. Lowe put a tax upon photographs? The Americans have done so for some years. Photographs yield a very large profit—the cost being something like 1s. 9d. per dozen, printing, &c.; the cost for chemicals for taking each negative little or nothing. This tax would not interfere in any way with the poor, and would not press heavily upon the public, if at all."

Photographers, doubtless, would be glad to learn from this astute political economist how to produce their negatives at a cost of "little or nothing." But, apart from such nonsense, although no definite project is before the public, it is just as well that photographers should be prepared to rebut the fallacious arguments and groundless assertions upon which the mere suggestion is based. The allusions to an American precedent for a photographic tax are most unfortunate, since the impost on photographs, originally applied when the country was suffering under the heavy expenses of a protracted war, was avowedly of a temporary character, and has since been removed. Further, the majority of the arguments which have been applied with justice and force against the proposed tax on matches, would tell with equal force in relation to a tax on photographs. The statement of the correspondent whose letter we have quoted, to the effect that the tax would not press heavily upon the public, if at all, is probably true; but on all true principles of political economy such a statement is fatal to the proposition. A tax to be just should press equally upon the public, and not upon a class. In this case the tax would be chiefly derived, there can be little doubt, from the pockets of photographers. The amount suggested for such a tax has generally been one penny upon each portrait, a sum it would be almost impossible to collect from the public. The average price of card portraits at the present time is at the rate of one shilling each, and at that price it is probable that photographers would be compelled to sell their productions still, as even if the attempt were made to charge the tax upon the public, the effect of competition would, doubtless, in a short time

compel the resumption of the normal price consisting of an even sum of money. The amount to which the photographer would be thus taxed would be, in many instances, most disastrous. The portraitist producing a thousand card portraits in a week would thus be taxed to an amount exceeding two hundred pounds a year. In smaller establishments, although the amount would, of course, be proportionately less, the effect of any additional taxation would be still more disastrously felt. At present there is, as we have said, happily no definite proposition for such an iniquitous tax; but as it is discussed, photographers should be prepared with good reasons against the imposition of a burden so unfair in itself, and so partial in its operation.

THE PHOTOGRAPHIC SOCIETY OF SCOTLAND.

ON another page we publish the proceedings of a meeting of this Society, which few of our readers can read without regret. It is a record of the closing acts of an old and once valuable society. Established early in the year 1856, and for a long time active and highly prosperous, the Society has now for some years been practically moribund, and it would probably have been some time since decently interred but for an unfortunate circumstance. The misfortune is not a common one: the Society is in possession of funds of which it knows not how to dispose. An accumulation of about five hundred pounds remains to be devoted to some suitable purpose before the Society can properly cease to exist. At the meeting in question, a proposition was brought before the members by the council, which, no one will learn with surprise, excited the murmurs of many present. It was practically a profound self-stultification, a confession that the whole purpose of the Society was a failure. The Society was established for the advancement of photography; its sole aim was to support and propagate the new art; and having done this for many years, it proposes now practically to say, "The advancement of photography is an end unworthy of the funds which have been subscribed by our members for that purpose; we will, therefore, hand over these funds for the purposes of another art, the devotees of which have often flouted photography, and denied its art claims, and we will remember photography no more." The council proposes first to have a portrait of Mr. Fox Talbot painted, and with the residue have a picture of some kind bought or painted, and presented to the Royal Academy of Scotland. Happily, several originally subscribed, and Mr. Tunny and others made some members most earnestly protested against such a diversion of the funds of the Society from the purpose for which they were very sensible suggestions in relation to the purposes to which the funds might, with propriety, be applied. We are not about to discuss the propositions now, but we cannot

but remark, in alluding to the subject, that there are two purposes, admirably aiding in the advancement of photography, with which the Photographic Society of Scotland has been especially associated. At its first annual meeting the distribution of presentation prints was declared to be one of its aims; and, for years past, the holding of exhibitions and distributions of medals for excellence in various forms gave an especial interest to the history of the Society. The proposal to devote a sum to the organization of an excellent exhibition, to be held during the meetings of the British Association,* was a very worthy proposition; and if something unusually tempting in the form of medals were offered in conjunction with such an exhibition, we think it would not be unsafe to predict for it a degree of success and interest which would be well worthy the effort. Recalling the idea of presentation prints with which the Society began, would it not be a noble purpose to form an album of the portraits of half a dozen or dozen of the originators of our art, to be distributed amongst the members of the Society, and possibly afterwards, in the hands of a judicious publisher, made accessible to the photographers of the world? How priceless to all interested in the art would be an album with fine large uniform portraits, the best accessible, of such men as Herschel, Talbot, Niepce, Daguerre, Reade, Brewster, Archer, Diamond, Ponton, Poitevin, and possibly others! A dozen ten by eight pictures, printed in carbon, bound in an album for presentation amongst all the members enrolled in the Society during the last few years of its existence, would not absorb all the funds at its disposal. It would certainly be an equitable mode of applying such funds, would certainly be in accordance with the original purpose of the Society, and would establish, if not a monument, at least a souvenir, recalling the Society and its purposes; and would be at once graceful, grateful, and honourable to all concerned.

Foreign Miscellanea.

The Vienna Photographic Society publish the regulations under which the medals for this and next year will be awarded. Two gold medals and two of silver are to be distributed, besides two extra ones of bronze, should the Committee consider such a course desirable. The rewards are the result of the Voigtlander fund, and can only be received by members of the Vienna Society. No clause exists as to the nationality of the candidates, and it is presumed, therefore, that any foreigners may compete for the honours, supposing they, in the first instance, enrol themselves as members of the Society. The first gold medal will be given for the elaboration of the best dry plate process which combines the qualities of sensitiveness and certainty. The gold medal for 1872 will be awarded for the best investigation and report upon the character of various kinds of gelatine, albuminate, resins, and other similar substances, such as are used with chromium compounds in heliographic processes. The silver medals will be awarded for different photographic studies.

The jury nominated by the Vienna Society in connection with the London Exhibition for this year are: Ludwig Angerer, Dr. Hornig, Dr. Heid, MM. Melingo, Haack, Homolatsch, and Antioie. A very fair collection of Austrian photographs is said to have been forwarded to South Kensington, which it is anticipated will fully sustain the reputation enjoyed by Vienna artists, especially in portraiture.

M. Santucek, of Znaim, has invented a lichtdruck process which allows of the production of heliographs upon

silk. At a recent meeting of the Vienna Society, Dr. Horuig exhibited some specimens of this kind to the members.

In Paris just now photography is being put to a purpose of a very painful character. The National Guards and Communists slain in the war, many of whom are but partially clad in uniform, are frequently unrecognisable after death, from the fact that their names and previous history are totally unknown to the officers under whom they serve. In this unsatisfactory state of things, it has been decided by the authorities to photograph all unknown dead bodies, and to attach such pictures to the registry showing the place of burial.

The three members of the Berlin Society for the Advancement of Photography, MM. Quidde, Schwier, and Petsch, who were attached to the German army during the recent war, have returned to their homes in safety, and, at a recent meeting of the Society, gave an account of their experiences in the field.

The *Mittheilungen* mentions, as a possible substitute for glass in photography, the compound to which Sonnenschein has recently called attention; he has found that when to gelatine and tungstate of soda in solution an acid is added, a tough mass is produced, which, after being thoroughly washed, becomes almost transparent. This mass has the appearance of glass, and is tough and pliable, especially at a temperature of 99° to 100° Reaumur, when it may be formed into any desired shape. A combination of the tungstic acid with the gelatine appears to take place. It is known that tungstic acid becomes changed by light, its yellowish tint being transformed to one of a greenish hue; but it remains to be seen whether this change will exert any influence upon the compound in question.

M. Löwy, of Vienna, has been very successful in the manipulation of Monckhoven's enlarging apparatus; many details of the process are said to be still unpublished by the author. Dr. Mouckhoven is just now residing at Leghorn.

M. Albert has petitioned the Russian Government for an extension of two years of his patent rights for the practice of his Lichtdruck process. M. Jacobi, of Neuendorf, near Coblenz, is said to have elaborated a mechanical printing method producing pictures without any visible grain.

M. Burger, who has recently distinguished himself as a clever photographer in connection with the Austrian mission in the East Indies, has been decorated by the Emperor of Austria.

An interesting collection of photographs has been made by the Vienna Photographic Society, which circulates among the members and the societies of the other towns, under the name of the "Wandering Album." The album contains novelties and pictures of exceptional merit, and represents very well the present state of photography as an art and as a branch of industry. Two series have already been collected of the album, and a third is now about to be completed, consisting for the most part of combination photographs from the studio of Messrs. Robinson and Cherrill. In reference to the subject of combination printing, M. Fritz Luckhardt recently exhibited a picture to the members of the Society, consisting of an interior, in which certain objects were shown whose presence under one roof was simply an impossibility, and for this and other reasons M. Luckhardt estimated that as many as a dozen negatives had been employed in preparing the picture.

A paper describing the qualities of various kinds of copal to be found in commerce appears in *Licht*.

An action has been brought against M. Steinhanser, of Prague, for publishing a little book on mechanical printing, mention of which was made in our "Miscellanea" some time since. The book purported to describe all methods now in vogue for Lichtdruck and similar processes. Messrs. Ohm and Grossman were the plaintiffs, but were unable to substantiate their charge.

A photo-relief process by means of which pictures of any

* Since the above was in type, an idea has struck us as well worthy of consideration. Why not hand part of the fund over to the British Association to be invested, the annual interest to pay for the preparation of a complete report of the progress of the art each year, to be supplied by a competent authority appointed by the Association?—Ed.

kind may be produced in relief is the subject of an invention by M. Knirsch, of Szegedin, in Hungary.

A new gold toning salt has been prepared by M. Pietschmann, of which ten grains, we are told, suffice for the manipulation of one sheet of albumenized paper; the price for which it is sold is rather less than four shillings per ounce.

A Russian amateur photographer, Baron Michael de Motilef, has invented a transparent pellicle to which the name of "Collodion glimmer" has been given. It may be used for the transfer of negative films and such like purposes.

AMERICAN CORRESPONDENCE.

UP MOUNT WASHINGTON—NEW USE FOR PHOTOGRAPHY.

Up Mount Washington.—Five hundred miles from Philadelphia to Littleton by rail; eighteen miles from Littleton to the White Mountain House in a sleigh by moon-light; a sound sleep and a good breakfast; then seven miles floundering through the unbroken snow, partly behind two horses on an old log sled, and partly (out of mercy for the horses) on foot, with my good friend Mr. B. W. Kilburn, the indefatigable and excellent landscape photographer of Littleton, N.H., I was at the foot of Mount Washington, eager to climb its forbidding height, and to stand upon its summit.

Previous to this winter the ascent of Mount Washington during the cold season had been considered an impossibility, and I remember well, when just a year ago I visited the White Mountains, and suggested the ascent of Mount Washington, my friend Kilburn answered, "*Why, you could not live there!*" But Professor J. H. Huntington, Assistant State Geologist of New Hampshire, having "lived" during the most of last winter on the summit of Mooseilank Mount, where he made meteorological observations for the Government, thought that Mount Washington, although much higher than the other, could also be mastered, and, therefore, organized an expedition to winter there. He carried his plans out fully, and the most gratifying success has been his reward.

Mount Washington is 6,291 feet high. There are inhabited places in America at greater elevations than this, but none so exposed to the fury of the elements as it is. It is only about sixty miles from the sea, and scarcely a day passes the whole year round without *some* sort of a storm being within a mile or so of, if not on, the summit. So liable are even the summer breezes which occur there to gently lift off the shingles from the few houses on the summit, that heavy chains are thrown over the roofs, and fastened to the rocks at each side in order to prevent the perpetration of any such sort of coquetry.

Well, we arrived at the cahia of the wood-choppers at the base of the mountain just at noon. We found the six sturdy wood-choppers at dinner. They were all once subjects of Queen Victoria, five from Ireland and one from Canada, and were living there as contentedly in the midst of the forests as we do in our great cities. The "camp" was governed by "Uncle Jim," who attended to the household duties, and was called the "old woman." He cooked us a fine dinner of fat bacon, and gave us with it molasses, bread, tea, and gingerbread. His vegetables, he regretted to say, were all gone. We ate what we could, and then, strapping camera, tripod, overcoats, lunch, &c., to our shoulders, we proceeded to make the ascent. As we entered the forest, it began to snow, but I was pressed for time, and we pushed on. The ascent was steep, and the snow under-foot deep and soft, so our progress was slow. After a while we got out of the forest among the stunted pines, and there we found the snow-crust harder, and able to bear us, also making it necessary to call our Alpine-stocks into requisition. The perspiration began to start, although our clothing was opened to our shirts. At the end of an hour we came to a little signboard among the trees which informed

us that we had climbed "one mile," and that two more still harder ones were still to climb. On we went, the snow falling thicker than ever, the trees growing shorter and shorter, thus giving the increasing wind fairer play at our ears and noses. It was not excessively cold, however, so we suffered but little. At the end of two miles no more trees were seen, and where the rugged rocks were not covered with snow, we had to clamber over their frosty, slippery sides. Now the snow almost blinded us, and we could see but a few feet ahead. We kept the railway track in sight, however, else we should get lost, for all directions are alike on a mountain side. As we neared the summit, the wind became furious, and the snow and frost hung upon our whiskers in great shapes, making us regular grey-beards. We had to lock arms in order to keep our feet, and from being blown away from each other. Thus we clambered the last half mile, and at the end of two and a-half hours we were inside the depot at the summit, wherein were quartered Professor Huntington's party, on whom we had come to make an afternoon call. The gentlemen inside heard our voices, and were a little surprised at our arrival, particularly in such a storm. The velocity of the wind was measured with the anemometer soon after our arrival, and was found to be 79.6 miles per hour. A person could not stand alone against such a wind. Of course, the storm prevented our seeing anything, and we had to content ourselves inside by the stove. The wind howled, and the timbers of the building creaked fearfully, but we were assured that that was only a gentle breeze compared with what they sometimes had to bear. If you have ever been on a steamer at sea during a severe storm, and in a state-room where you could hear the grim grinding of the machinery, then you have an idea of what it was like on the summit of Mount Washington during a March gale and snow storm. I awoke often in the night, and the same fearful howling, buzzoo! buzzoo-o-o! was going on, promising to be perpetual. Not perpetual, however, for, arising early in the morning, we witnessed the grandest sun-rise that mortal man, perhaps, ever saw. Although it was clear above us, the clouds below were still busily floating around like great armies preparing to break camp, some sailing in one direction, some in another. Away off towards the sun there were some great snow clouds shifting about, as if not knowing where to turn. Suddenly their grey heads would become illuminated with the most brilliant red and golden light. The next instant they would be torn asunder like the parting of a lace curtain, and the sun would scatter his gorgeous light all over them. Some parts of the clouds would then arise, like the spray of Niagara, carrying the gorgeous colours with them; others would descend, on which we saw the most beautiful rainbows, and the sun, half risen only, would for a moment shine unobstructed. Again a thick cloud would cover the sun, and the same operation would be repeated. This was done several times at short intervals, the sun battling with the clouds for the mastery, and mowing them down as a line of musketry mows down humanity. After the struggle was over, the clouds gradually scattered and then arose again, leaving the valley below us all clear to the sea. The ocean could be seen with the naked eye, and with a telescope the ships entering Portland Harbour and the people cleaning snow from their pavements in Gotham could plainly be discerned. It was a curious feeling to see the sun shining so brightly far below us, while about us its rays had not reached. Another curious sight I must record. South of us, a half mile or more below the summit, hung a heavy bank of snow cloud. In the centre of it was a great opening, and through it we could see the bright sunlight shining on the valley below. After the sun-rise the breakfast was despatched with an excellent zest, and then I spent hours roaming about the summit, taking in the wonders around and below me. It was necessary to run in often and get warmed up, for one freezes quickly up there. The snow had nearly all blown off the mountain top, thus giving the best opportunity of seeing the beautiful fros^s

formations that attach themselves to every rock, house, telegraph pole, and so on, on the summit. One never tires examining them. They are shaped like the wings and tails of birds, and are of the purest white. They vary in size. Their extreme end points horizontally to the surface to which they are attached in the direction of the wind. They are neither snow nor ice, but masses of frost, as pure as alabaster and as beautiful as the wings of angels, for they must be like them. Over and around the summit we travelled, time and again, now opposed by the cutting wind (which had fallen to forty-four miles), then pushed forward by it, taking in what we could of the wonders about and below us. We climbed up a snow drift to the top of the Summit House, and sat astride the ridge pole, a feat not done daily. The great gulfs, long miles below us, looked to be within snow-ball distance, and hundreds of unnamed mountains slept in their white quiltings beneath. We did not go prepared for a regular photographic excursion. We carried up thirteen Liverpool dry plates, however, and exposed them all. The wind was somewhat against us, and, on development, we found it had spoiled some of our plates. We erred in exposure somewhat, too, making the exposures too short. That error, however, is one of the delectabilities of the dry method, and we expected it. Mr. Kilburn was not to be baffled by any such circumstance, though. A week after we were there together he made the ascent again, laden with a quantity of wet plates, and all necessary things to work them. At this writing, he is still there, and has been there nearly two weeks. I learn from him by telegraph that he has secured some excellent negatives and prints, from which he will send you shortly.

After a good farewell turn over the summit, and after exposing all our plates, we prepared to make the descent, for threatening clouds hovered over us, and we feared a freezing rain more than snow.

The room in which our hosts live is in one corner of the depot building, well protected, and is about eleven feet wide by twenty feet long, and eight feet high; it serves as kitchen, parlour, sleeping apartment, and observatory. Two small windows light it, and when they don't, coal oil does. Two stoves are required to heat it when it is very cold, and sometimes only one is used. My regret was that I could not stay longer.

I could tell you much more of the work of the parties there, but my space will not allow. Meteorological observations are made three times a day, and telegraphed to the Signal Service Department at Washington. By this means the approach of storms is foretold, and many lives saved from loss at sea.

We bade our friends farewell, and were soon out of their sight, descending rapidly to the "regions below." The descent was more pleasant than the ascent, for there was no storm, and we had a clear view. It was more perilous, though, and constant watching was necessary lest we fall or sink in the snow. We arrived at the base one and a-half hours after leaving the summit, took tea again with the wood-choppers, and then walked back to the White Mountain on snow shoes, accomplishing the trip in half an hour less than the horses did for us coming up. We drove at once to Littleton, and next morning at nine o'clock I was on my way to Canada. Of what I saw in Montreal, Toronto, and so on, I must tell in my next, for space will not permit.

New Use for Photography.—I must tell you, before closing, of a new and ingenious use made of photography in our own goodly city a few evenings ago. If you will recollect, at the intersection of Broad and Market Streets, there are four blocks of ground that have been occupied as public parks. Some of our "city fathers" desired to build the public buildings on this ground, and thus block up the intersection of two of our most handsome thoroughfares. This proposition excited the indignation of our citizens, and a mass meeting was called to oppose the project. The first hour at the meeting was occupied by exhibiting in

the lantern views of some of the streets in European cities, which were intended to show how our coveted space could be improved, and made an ornament to the city. Photography, as usual, triumphed, and the vote of the people was against the "city fathers."—Truly yours,
Philadelphia. EDWARD L. WILSON.

THE TEMPER OF THE OPERATOR, AND EXPRESSIONS IN PORTRAITURE.

BY ELWOOD TERRY.

I do not doubt that several papers have been written on this very interesting subject; yet if, by a few practical remarks, I can draw the attention of the operator so that he may improve the expression of the subjects that come under his control, I shall be forgiven having occupied a small portion of your valuable journal.

Everyone is ready to admit that, next to position, we look to the expression of the sitter; and it depends to a great extent on the expression as to whether the sitter will be pleased with his photograph. We all know a photograph may be admirable in position and excellently lighted, but still be disagreeable from the want of (as the public call it) a nice expression. I have met customers in a bad temper, when they have said, "I don't care for my carte, Mr. —; I think it is very bad indeed." I have then, in no very amiable manner, asked their reason for disliking the same. The answer, as a rule, is, "Well, I cannot complain of the photograph, and the position is good, but this is not my expression; you must see that for yourself, Mr. —. In fact, none of my friends like it, and I should prefer to be taken again." I found this occur so often that it became quite a loss to me. In fact, I was getting quite sick at heart about the matter until a friend came in and said, "May I give you a word of advice?" "Certainly." "Well, you are losing your customers through your bad temper." "Indeed, I was not aware I was bad-tempered." "But it is so," said he. Several of my friends have complained to me about it; at last I felt convinced it must have been so.

I found I had been so bent on getting at clear manipulation and good effects from lighting, that I had overlooked, to a certain extent, the expression and feelings of my customers, at times treating them like so many blocks of stone to be moulded after my own fashion. Invariably I managed to get good pictures and good expression when I had before me a beautiful subject, because I appeared before them using my best manner. I was pleased to gratify their slightest wish. They had but to whisper they would prefer two positions, and immediately I acquiesced, not daring to say nay, because he or she was handsome, and would make a good specimen. But woe to the person coming in that would not photograph well! My manner was altered, voice changed, and I at once acted on the defensive.

I am happy to say this is now almost done away with. I had several battles before I was at all successful. Now I strive to the utmost to photograph the plain subject the best; and I can safely say, since doing so, it has been a source of satisfaction, both pecuniary and otherwise. Therefore, I should advise operators to curb their tempers, not to be haughty with customers, treating all civilly, the rich alike with the poor; to study all sitters as they enter the studio, entering into conversation with them, causing them to feel, if possible, as though they were at home; and, whilst so doing, finding out the best position of the face. Have the plate at hand ready by the time the subject is placed in position, because, when kept waiting, a vacant expression is certain to come over the face. If delayed at the time from exposing the plate at once, before taking off the cap from the lens draw the attention of the sitter to any object there may be in the studio, asking his opinion upon it. It is very remarkable the change that is at once noticeable in the countenance. A musical album is a very

good accessory in the studio of the photographer. It gives to the person that hears it for the first time a bright, easy expression, laughing or sombre expressions being objectionable. A face in repose is the expression most to be aimed at. No time need be lost in trying to please customers. You can engage in small talk with them whilst moving the background, placing the head-rest, &c. By so endeavouring to please, the confidence of the sitter is gained, and the operator may have no anxiety as regards the result when the plate is developed.

ON LARGE PHOTOGRAPHS.

BY EDWARD DUNMORE.*

In a paper read at a recent meeting of the South London Photographic Society, attention was called to the advisability of *habitually* producing a larger class of photographs than has been hitherto the rule. Pictures the size of a full sheet of paper—say two feet long, or larger—I am inclined to think would cause photographs to be considered by the paying public not only of more real value, but a better investment for their money than the smaller productions we have hitherto been in the habit of seeing. Say what we may about the science and æsthetics of photography, the *progress* of it depends more, perhaps, than we feel inclined to allow, upon the £ s. d. considerations thereunto attached. Given the demand, the supply will not only increase in quantity, but in quality, for, I believe, in photography the motto "Qualitas, non quantitas," will not apply, but for the "non" we must substitute the "et." A surfeit of inferior work is much more readily induced now than formerly; and, with superior work, we may safely predict an increase of demand in proportion to the increase of excellence. The advantages of large photographs (now that the bugbear of non-permanence has been somewhat laid) are manifold and evident. The principal claim that can be advanced for them before all others is on the score of art-excellence, for the most beautiful effects presented by nature can never be so adequately rendered in a small picture as in a large one, however skilful the photographer may be. Perhaps few photographers have seriously thought of making large pictures of the kind and in the manner to which I allude; if they had, the supposed necessary gigantic apparatus that would be required suppressed any active endeavour to carry out these ideas, so, "like the baseless fabric of a vision," they melted into air.

If we set ourselves seriously to consider this matter, many of the difficulties will prove groundless fears; but what great success was ever achieved without some difficulty? And in this matter so much extra skill would mean so much extra pay, as well as extra praise. Thus much for the reason why we should turn our attention to large pictures.

The first important consideration is undoubtedly the cost. Can such pictures be produced with little or no extra outlay or reconstruction of apparatus now in the hands of photographers? I am inclined to think this problem can be satisfactorily answered in the affirmative; at the same time, as our requirements became manifest, so would contrivances start up to lend a helping hand. When it is found that care and skill, not money or money's worth, are the principal considerations, hundreds will "go in" for large pictures with more or less success. We have become accustomed to have our portraits enlarged with no loss of definition when the original negative was absolutely sharp. Why should not our small landscapes be served the same? There are no objections; but instead of having, as is usually the case with portraits, a positive print, we require an enlarged negative, for, in addition to the sharp correct enlargement, we must have the power of altering, modifying, and adding. That can only be practicable by contact printing; and these alterations, modifications, and additions must be made by the artist himself, who will diffuse his own individuality into the work—in fact, make the picture.

We will now consider the kind of negative most suitable. Paper negatives I am inclined to think the most practically useful. Large sheets of glass are not only expensive, but dangerously fragile; moreover, paper negatives answer every purpose, and exceedingly good definition can be obtained with them; so much so, that I question if a print from a thoroughly good one could be distinguished from one printed from a glass negative. I do not suppose paper negatives will ever supersede glass for direct field work, but, in this case, where the time of exposure and size of picture are of less manipulatory consequence, every advantage is to be gained by the use of paper. With regard to the manufacture of paper negatives, I am not sufficiently practiced to offer an opinion as to the best way of proceeding; I think this would form a very interesting subject for a paper from some practical man; for, should the ideas now enunciated be generally adopted, many would feel anxious for information on this head.

Before the preparation of the large negative, the small original will engross our careful attention. It must possess perfect sharpness, and be devoid of any granularity. Sharpness or definition cannot be obtained in the ordinary way on the usual ground-glass focussing-screen with anything like sufficient accuracy; we must substitute a semi-opaque, non-granular surface, which may be obtained in many ways. One is, by pouring suitable solutions (gutta-percha and lac in benzole, for instance) on clear flat glass, and drying; however, the more perfect this surface the better. The focussing must be done with a good magnifier—say a power that would increase the image to as large size as the intended completed proof. In fact, too great care cannot be taken to secure a perfectly defined negative.

When this part has been satisfactorily accomplished, the development of the picture next claims attention. Our ordinary iron solutions are inapplicable, producing much too coarse a deposit, although the addition of gelatine and its compounds materially improves it. A few experiments in this direction would be advisable to prove what combinations would produce the finest deposit. There is absolutely no granularity with pyrogallic development, but if the developer in common use could be modified so as to become suitable, it would be a decided advantage, for almost every photographer is accustomed to use iron for wet-plate work. A sort of rough estimate of the quality of the deposit may be formed by examination of the colour. The white-looking negatives are always much coarser than the dark ones, as the finer the deposited silver the darker the colour. In ordinary printing these slight differences are of little importance, but in this class of work no granularity is a *sine qua non*. A transparency from this negative must be obtained by contact-printing on a dry plate. I think this the best method to ensure as perfect sharpness in it as in the original. This transparency is to be used for enlargement to any required size.

Having now considered the necessary manipulations, due attention to each point being carefully accorded, the selection of the view to be enlarged must rest with the artist, and few directions can be placed on paper so as to be of any practical use; nearly all must depend on his knowledge of art practice and art feeling. He must imagine and decide, from nature spread out before him, and from the effects on the focussing-screen, how much smaller than the one, how much larger than the other, his intended work will be, so that the lights and shadows will be properly distributed, massed, and arranged, bearing in mind that however suitable such dispositions of form, light, and shade may seem for a small picture, it in nowise follows that this suitability will apply to the larger copy. Here art knowledge is indispensable, and a brilliant, well-trained imagination of the highest importance.

I will not now further trespass on your time, but submit these few remarks to your careful consideration, hoping that the walls of our next exhibition will plentifully teem with large and important artistic photographs.

* Read before the Photographic Society of London, April 11th.

I have had lent me by Mr. Bovey a few enlarged negatives, enlarged from half plates by Mr. Hopkin, of Wimborne, Dorset, which will, I think, bear out my assertions as to the necessary sharpness being obtained.

[The pictures exhibited by Mr. Dunmore were a view of Stonehenge and other landscapes, enlarged to the full extent of a whole sheet of paper. Both negatives and prints were eminently satisfactory, both on the score of sharpness and pictorial effect. The former had been rendered transparent (for greater facility in printing) by subsequent treatment with melted paraffine.]

THE AUTOTYPE PROCESS.

BY TOM TAYLOR.*

THE employment of the autotype in this country is still rudimentary in comparison with its possibilities. Nothing has as yet been done here comparable, in artistic importance and extent, to the great work of Braun at Dornach. But the work of the Autotype Company is progressing here in different directions, all for various reasons useful, interesting, and, both commercially and artistically, important.

Its durability renders the process trustworthy for reproductions of the treasures of public institutions like South Kensington and the British Museum. Some of our choicest possessions—in the way of drawings and engravings—in public galleries, museums, and private collections, are, by its help, being brought within general reach. The masterpieces of Marc Antonio, and his early Italian school of engravings, have already been reproduced in autotype, and students thus furnished with examples eminently calculated to educate the eye to appreciation of fine drawings and pure outline. Then, as examples of effect in engraving, as good in their way as Marc Antonio's are of drawing, permission has been given to reproduce by the same means some of the rarest of the engravings after Sir Joshua in the British Museum.† So the fine collection of Albert Durer's engravings and drawings, lately exhibited at the Burlington Fine Arts Club, is being now reproduced by this process, as is the celebrated Salamanca collection of prints after *Nielli*, more than fifty of which are unique and undescribed. Another valuable reproduction is that of Turner's *Liber Studiorum*, which has been eagerly bought up. In like manner has been published a reproduction of one of Hogarth's series—"The Idle and Industrious Apprentice"—from a fine example in the Museum. In this way not only may art rarities like these be made accessible to the general public, but all risk may be averted of the utter annihilation of unique works so long as autotypic facsimiles can be preserved. Some may think this dissemination of rare things a doubtful advantage, contending that their rarity is what gives them their especial charm as well as value; that "being wanted they will be more wondered at;" and that you cannot popularise such gems without, in some degree, vulgarising them. But I think it will be generally admitted that one of the objects of education now-a-days should be to open as many minds as possible to the refining influences of art; and that whatever enables us to bring fine examples of drawing and engraving within the reach of the million is a powerful instrument for this purpose.

Again, it seems to me evident that, even in defiance of difficulties of colour, reproduction of pictures by photographic means, supposing durability secured, has immense advantages over translation by engraving; at least, I have never compared photographs of pictures or frescoes with even the finest engravings without feeling that the former conveyed to me a new sense of the power, significance, and beauty of the original work. In Paris—always quickest to avail herself of new applications and discoveries in art-industry—the use of photography, instead of engraving,

as a means of reproducing the popular pictures of the time, has become universal. So in Germany—at Munich, Dusseldorf, and, above all, at Berlin—an enormous demand for such photographs of pictures has grown up. There is no reason why this should not be extended to England; why the best pictures of the year should not be autotyped, and spread broadcast over the kingdom and its dependencies, and even abroad, where now, save Wilkie and Landseer, even the names of English artists are unknown beyond the narrowest circle of *art experts*. How successfully the autotype can replace the engraving may be seen from the autotype reproductions already published of pictures by T. Faed, Lucy, Cave Thomas, Erskine Nicol, and others. The autotypes of Mr. Macnee's full-length portrait of Lord Bellhaven, and Mr. James Sant's of Mr. Capel, seem to me quite as good as even the best mezzotints; though this is a bold thing to say with S. Cousins still in the field, and with the recollection fresh in me of Barlow's admirable plates after J. Phillips' portrait of A. Egg, and Millais' of J. Fowler, the most effective portrait-engravings, if I may speak my own opinion, of our time. Again, as illustrations of the power of autotype in rendering very different classes of pictures, take the reproductions of Mr. Marcus Stone's picture of the "Princess Elizabeth at Mass," and Mr. Beavis's "Militia Train, in the Time of the Civil War, conveying stores to Elizabeth Castle, Jersey," and Mr. Wheelwright's "Her Majesty's Buckhounds," all to be seen at Rathbone Place.

In France it is a common practice for painters to make a monochrome drawing of their pictures for the photographer. To secure a correct effect and balance of colour, under certain conditions this may be necessary. But it is wonderful to see with what success—thanks to extreme care, good light, and perfection of lenses, and all other appliances—the autotype process has been applied to reproduction from the picture directly. The autotype after Mr. Marcus Stone's picture above noticed, from a drawing in monochrome, seems to me inferior in sharpness and rendering of the original to the autotypes after Beavis and Wheelwright, which are from the pictures themselves, and there seems to be no limitation in the size of the work producible by this method. It is especially for the reproduction of drawings and sketches that the autotype ought to be as available to artists of the time as in the case of masters passed away. The perfect facsimile of a sketch of a beautiful child's head by Sant, to be seen in the gallery at Rathbone Place, shows what may be done in this way. How much better to be able to distribute among friends a facsimile of a fine chalk drawing by Richmond, or Watts, or Sandys, than a photograph with all the sitter's natural imperfections sharply set down, perhaps exaggerated, and without the genius of the painter to elevate homeliness into interest! In this way we might disseminate fine art with our friendly souvenirs.

The field of book-illustration, too, is a wide one, which the Autotype Company is already working on a considerable scale, and which promises to grow into great commercial importance. Under the supervision of Mr. Fleming (the Company's Factory Director) the uncertainty and inequality of impressions are being gradually got rid of in practice. The illustrations in this number are produced by the autotype process.

Operators trained to the ordinary photographic processes, naturally wedded to their old methods, even where they are not commercially interested in resisting the introduction of new ones, used to complain that autotypic prints were inferior in sharpness of definition and brilliancy of effect to those taken by the various less durable methods in common use. But I am not at all sure that, if the complaint were just, it would hit a defect; for to artistic eyes, as distinguished from photographic, one of the great faults of most photographic work is excess of sharpness and definition. Hence, artists almost invariably prefer work like that of Mrs. Cameron, in which sharp focussing is intentionally avoided, to the clear-cut "brilliant" work of the enthusiastic photographer proper, who looks on a blurred or cloudy effect as a

* Continued from p. 188.

† This series, however, was executed under such unfavourable conditions as to light, that it gives a very inadequate impression of the capacity of autotypic reproduction.

failure and an offence. All such questions, however, are now set at rest by recent improvements, resulting in glazed autotypic prints of landscape and architecture, that seem to me even to surpass in brilliancy, depth of colour, and delicacy of gradation, the finest silver prints I have seen. For my own part, I greatly dislike these glazed surfaces, which seem so dear to professional photographers; and I cannot but regret that the Autotype Company should have found it necessary to show their power of excelling the latter even in their most inartistic points of practice. Even were the autotype less able than it is to hold its own against the usual processes, it has the immense advantage of admitting all varieties of monochromatic colour, with a durability equal to that of the pigments it employs, among which it has a large choice of permanent colouring matters.

Containing these advantages, it seems to me that the future of the Autotype process, both commercially and artistically, should be one of assured success and world-wide usefulness.

THE COFFEE GUM DRY PROCESS.

THAT the coffee-gum dry process of M. Constant Delessert is a sound and practical method there can be no doubt whatever in the minds of those at all conversant with the manipulation of dry plates; and to those who have no such experience, the simple affirmation of such a careful investigator and accomplished photographer as M. de Constant is sufficient to inspire perfect confidence. Every stage of the method and every manipulation has evidently been critically studied by the author, and we may well rely, therefore, upon the recommendations and instructions which have been written down for our use.

Although we have not yet had opportunity of essaying the method put before us, our experience of the gum-gallic and coffee processes, of which the Constant method may be said to be a combination, are such as to make us hope for very uniform and perfect results. M. de Constant tells us that out of one hundred plates exposed by him last summer not one single negative had to be rejected on account of imperfect preparation or defective sensitiveness, and only three or four of the pictures taken were of so mediocre a quality as to necessitate their being put on one side. When we remember the excellent landscape work of M. de Constant, his charming little views of lake and mountain scenery, printed for the most part upon rough-faced paper, and reminding one forcibly of the sketches of Gordon and England, the evidence thus offered is by no means unimportant. His essays and results with coffee alone, which for a considerable period has been M. de Constant's favourite method, practised in its primitive form as first suggested by Colonel Baratti, were such as to leave little to be desired, and his pictures with the coffee-gum process are even superior to these.

M. de Constant does well in not passing over lightly the difficulties attendant on a dry-plate process. He frankly admits there is much to be done in the preparation of the plates, in washing and drying them, and that proper care and attention are necessary to their successful production. But then, he argues, by their use, in most instances, much time and trouble are saved, which more than compensates for the solicitude lavished on them in the first instance. He dwells at some length upon the difficulties encountered by the wet collodion operator in the field, on the many inconveniences to which he is put, and the makeshifts to which he must have recourse in the coating, sensitizing, and development of his plates, while the photographer furnished with dry plates, instead of finding his tour disagreeable and wearisome toil, regards it simply in the light of a promenade. It is only upon the point of certainty of result that any argument is admissible, and here M. Constant says that the process is at once so simple and reliable, that as such confidence may be placed upon it as upon the wet collodion method itself. This must, however, neces-

sarily be always one weak point—the only one possibly—with dry processes, which it is impossible wholly to remove, and all that can be done is to reduce the chance of failure to a minimum, a circumstance already seemingly accomplished, if we call to mind M. Constant's results.

Two hours are given as the period necessary for the preparation of a dozen plates. We can easily believe, with the author, that this time is not thrown away, and is again saved in the further manipulation of the plates; but inasmuch as the prepared films are said to be endowed with excellent keeping qualities, it is open to question whether the time and labour could not be saved to the operator altogether. The preparation of dry plates always involves some skill and experience, even if the operator has always the requisite time necessary to the manipulation at his disposal, and for this reason we cannot help thinking that it would be a great boon if such requisites could be procured commercially. No difficulty seems to have been experienced by the Liverpool Dry Plate Company to supply a serviceable product of this kind, and it would be well if photographers could have some choice in the purchase of dry plates. Of course, in very many cases operators prefer to prepare their own working materials, but in other instances the arrangements and requirements to be attended to at the outset are such as to frighten the more timid away from the matter altogether.

Although M. Constant states that the coffee-gum plates may be preserved for two or three months, he recommends their development soon after exposure—say within the next four and twenty hours. So early an attention we should have thought scarcely necessary, seeing that both with plates prepared with coffee and with gum a few days' interval between exposure and development is of little importance. Indeed, coffee plates we have kept for three or four weeks after exposure before development, and the negatives thus obtained have possessed all their original detail, exhibiting, at the most, a slight tendency to assume a positive appearance. In our experience, if dry plates have been fully exposed—and it is always a safe plan rather to exaggerate than shorten the pose—the lapse of a day or two afterwards does not influence the character of the image in any apparent degree. We quite agree with M. Constant that harmony and delicacy are unobtainable with short exposures, and that length of pose is often an advantage with a dry-plate process rather than a defect.

Before concluding our few remarks, we must not forget to compliment M. de Constant upon the completeness of his investigations. When we remember that he has been a constant dry-plate worker for several years, and has patiently experimented with almost every method of this nature that has of late been made public, we know we may fully rely upon his experiences, more especially as his previous teachings which have been published have always been characterized by much ability and honesty of purpose.

PRACTICAL EXPERIMENTS WITH COLLODION.

COMMUNICATIONS FROM THE PHOTOGRAPHIC STUDIO OF THE ROYAL INDUSTRIAL COLLEGE AT BERLIN.

No. 1.—TO WHAT EXTENT SHOULD COLLODION BE IODIZED?

BY DR. H. VOGEL.*

It is a known fact that when too strongly iodized, collodion produces a film of iodide of silver which adheres but imperfectly to a glass surface; and is, moreover, prone to become covered with thick yellow streaks. In order to discover the degree to which the iodizing of a collodion can be carried, I prepared a normal collodion of the following proportions:—

Pyroxylin	3 parts
Ether	75 "
Alcohol	125 "

* Photographisches Mittheilungen.

Of this collodion I took six samples, and added iodizing salts in the following proportions:—

No. 1.	2 grammes Cd I.;	1 gramme Na I.;	1 gramme N H ₄ Br.	to 320 grammes collodion.
No. 2.	The same iodizing salts	to 240 grammes collodion.		
No. 3.	"	"	200	"
No. 4.	"	"	180	"
No. 5.	"	"	160	"
No. 6.	"	"	140	"

No. 6 collodion yielded plates having yellow striped markings, and dried very slowly after being poured upon the glass; No. 5 gave also similar markings, but of a less pronounced character, and dried more slowly than No. 4. This latter sample worked clearly, as likewise did Nos. 3, 2, and 1.

In the strongly iodized plates the pictures came out much more rapidly on development than with those containing a less quantity of sensitizing salts. The developed images were, in the cases of Nos. 5 and 6, very much harder than in No. 4. Between examples 3 and 4 there was no appreciable difference; but, on an average, No. 3 yielded the best results. The weakly iodized collodion—samples 1 and 2—yielded, in like manner, clean plates scarcely inferior in sensitiveness to No. 3. By decreasing the amount of sensitizing salts to a still further extent, the plates exhibited a tendency to become fogged, and then became insensitive.

According to these results, therefore, a collodion of the nature under trial should contain not more than 2.22 per cent. of the above iodizing salt as a maximum proportion; when containing between 1½ and 2 per cent. of the salts very good results are obtainable. Of course, with a collodion differently constituted, and with more difficultly soluble iodizing salts, the proportions would differ materially.

II.—ON THE SENSITIVENESS OF IODIDE AND BROMIDE OF SILVER.

About six years ago I instituted a series of experiments upon the action of bromine in collodion, and proved, by the aid of a white bust surrounded by black drapery, that pure iodized collodion was the more sensitive to the brighter portions of the object, while bromo-iodized collodion rendered the darker parts of the model the more perfectly. From this I concluded that iodide of silver was the more sensitive for bright rays, and bromo-iodide of silver for the darker or more subdued rays. For this reason it is that a mixed collodion invariably works softer than the pure iodized material. In the recent publication of Dr. Schultz-Sellack, a communication of much scientific and practical value, the writer endeavours to trace back these differences in the behaviour of iodized and bromo-iodized collodions to their respective sensitiveness to the various colours. Iodide of silver is only sensitive to the blue and indigo colours, while iodo-bromide of silver is impressionable by blue, green, and the tints even beyond these in the spectrum. Now it so happens that the darker portions of our models—or, in other words, the shadows—are lighted up from the reddish green reflected light emanating from the walls of the studio, while the high lights are illuminated by the direct violet rays and brighter light of the sky, and hence the extensive action of the bromo-iodide of silver in reproducing the shadows. Such an explanation is worthy of attention, but, at the same time, it hardly answers under every circumstance.

Relying upon the fact that iodide of silver alone yields a very hard picture, several of my pupils have employed the same in the reproduction of engravings, where a hard negative is especially desirable. Curiously enough, it was found that iodide of silver employed with a lens that had been stopped down considerably yielded a much thinner picture than bromo-iodide of silver, and for this reason, therefore, the former salt was inapplicable to the purpose in question. In this case, therefore, it is evident that while the intensity of the light is lessened by the use of a small

diaphragm, no modification of the colours takes place. The slight sensitiveness of pure iodized collodion for weaker light rays receives hereby greater confirmation.

To prove this more definitely, I obtained a Busch stereoscopic camera, and placed the same in front of a Woodbury-type print of a bluish-black colour, focussing the same sharply, and stopping one of the lenses down with the smallest diaphragm, while the other remained with full aperture. The light intensity of these two pictures upon the ground glass was, under these circumstances, of course, very different, and was, indeed, in the proportion of one to twenty-eight, calculating from the size of the two openings. A plate coated with iodized collodion, and another with bromo-iodized collodion, were then exposed, one immediately after the other, to the double image, for a period of fifteen seconds, the first collodion containing three proportions of iodine, and the second two of iodine and one of bromine.

The difference in the results was very marked. The iodized collodion yielded a very quickly developing but hard negative of the light image, and but very slight traces of the stopped down object; while the bromo-iodized collodion gave a more slowly developing and softer image of the more illuminated object, and of the darker one a more vigorous reproduction in the high lights than in the iodized collodion. The experiment was subsequently repeated several times, and with similar results. As in this instance both images of the object were of the same colour, and differed from each other only as regards brightness of illumination, the greater sensitiveness of bromo-iodide of silver for weakly illuminated objects is clearly proved. An explanation of this phenomenon is not easy.

Observations of a similar nature were made by Bunsen with chloride of nitrogen. Subdued light has at the outset no action whatever on this compound, but after exposure to light for some minutes a change takes place which, with very strong light, is brought about at once. It is just this action at the commencement which is of importance in photography, especially with short exposures, and it would appear that the action commences earlier with bromo-iodide of silver than with the iodide salt. That the present bromide of silver is more easily decomposable by light than iodide is in no way antagonistic to this circumstance. The easily decomposable bromide of silver introduced into a mixed collodion accelerates the decomposition of the iodide of silver present in the compound, and it is the latter salt which, on account of its greater capacity to blacken on development, renders this action visible.

PRINTING BY THE AID OF CARBONATE OF AMMONIA.

BY DR. VOGL.*

SOME time ago I suggested that instead of fuming with ammonia, the employment in the printing frames of carbonate of ammonia should be substituted, when but small quantities of work had to be performed. A piece of thick black cloth is placed upon the sheet of sensitive paper in the pressure-frame, and powdered carbonate of ammonia is sprinkled over it as uniformly as possible. On further experience with the use of this salt I have found that when the salt is allowed to stand in an open vessel exposed to the atmosphere for several days, its virtues disappear in part, and the prints obtained lack force and vigour. The reason of this lies in the fact that commercial carbonate of ammonia consists of two different salts, viz., monocarbonate of ammonia, and bicarbonate of ammonia. The former is readily volatile in the atmosphere, being decomposed into one equivalent of carbonic acid and one equivalent of ammonia, and the less volatile and active bicarbonate of ammonia thus only remains behind; only half of the salt is, under these circumstances, made use of, and it is obvious, there-

* Photographisches Mittheilungen.

fore, that the powdered salt must not be allowed to remain open to the atmosphere.

To institute an accurate comparison between the methods of fuming the paper and placing the powdered salt in the frames, I printed some paper treated in the two ways at one and the same time. The action appeared the same on both when the sheets had been freshly fumed, but if the latter remained a couple of hours exposed to the air before printing, they did not give such good results as were obtainable by means of the ammonia powder.

That ordinary sensitized paper, after fuming, prints more rapidly than an unfumed material is well known; but a circumstance that struck me very forcibly in this kind of work was the extraordinary brilliancy of pictures produced by means of a weak sensitizing bath. A stinking albumen-paper which, alone, yielded but flat, monotonous pictures, gave, when treated with carbonate of ammonia, the most splendid results, of surprising intensity, darker in the shadows and brighter in the high lights than prints produced with ammonia; so marked was the improvement in every way, that I can confidently recommend this mode of proceeding in all similar cases. In working with strong positive baths the difference in tone and brilliancy is not so marked.

One point in connection with ammonia printing is worthy of notice: the pictures assume a much browner tint, and take longer time to tone.

Finally, I tried the sensitized and washed paper recommended by MM. Haugk and Baden; the sheets were sensitized upon a somewhat strong bath (1 to 10), and washed in the manner described by those gentlemen. The paper printed, with the aid of carbonate of ammonia, more rapidly and brilliantly than ordinary paper sensitized on a bath of the same strength, but the prints toned somewhat more tardily.

Correspondence.

CRACKED NEGATIVE FILMS.

SIR,—Whilst the discussion is going on in your pages on the cause of vermicular cracks in the negative film, I am tempted to send you an account of my own experience of this trouble.

Some seven or eight years since, I called in at a photographer's studio; and, whilst in conversation, he drew my attention to what I considered a remarkably fine quality of colourless plate glass. This, I think I understood at the time, was of foreign manufacture. However, as he kindly offered to allow me to do so, I brought away a dozen quarter-plates, in order to try them, intending, if, as I supposed, the printing qualities of the negatives taken upon this glass were superior to those upon the usual green tinted glass, to get a larger supply. I used them up at different times along with my other plates, mostly selecting a colourless glass when I wished for a negative of more than usual value. I soon discovered that these glasses did not possess, as I had expected, any great advantage in printing qualities over the ordinary plate glass, and, consequently, I did not order any more. My plan has invariably been, to tie my negatives, after writing the date when taken upon them, in separate paper parcels, with two leaves of blotting-paper between each two negatives, to protect the films. Each of these packets would, on an average, contain four negatives or portraits, representing that day's work. The names and dates were entered in a book for easy reference. Many of these negatives, after yielding a few prints at the time, have been stored away carefully in a dry place for seven or eight years. The other day I had occasion to open one of these packets, when, to my great disappointment, I found the negative I wanted—ono taken upon the white plate glass above alluded to—completely covered with the vermicular markings. The other three negatives in the same packet, taken on green tinted glass, were as good as when first taken. I did not at this time suspect the glass, but I extended my investigation through this box, and the result was, that I found in five other packets (each of from four to six negatives), nine on colourless glass, and all similarly affected. In each packet the negatives taken on the common kind of glass, on the same day, by the

same chemicals, and, indeed, under precisely the same circumstances and conditions, were in a perfect state of preservation. I think, as regards the quality of the chemicals I was at that time using, it is only necessary to say they were from the well-known establishment of Mr. Thomas, of Pall Mall. I think, sir, you will allow that, in my case, at least, the glass on which the negatives were taken must have been a primary or secondary cause of the defect alluded to.

Now I think of it, I believe some one—probably Mr. Dallmeyer—referred in your pages a few years back to the possibility of certain kinds of glass being liable to affect the negative whilst it was "sweating."

My photographic recreations are necessarily limited, and frequently carried on at long intervals; so that I only throw my mite of experience in for what it is worth, and by way of testifying, in some slight degree, my gratitude to the NEWS for much valuable information and considerable amusement during a series of years.—I am, sir, your obedient servant,

Kilbourne, near Derby, April 18th.

J. H. WOOLLEY.

THE GRAPHOGENIC.

SIR,—How very aggravating it is, after spending much thought, time, and money (as I have) in contriving my new tent, to find my labour vain, my hope of astonishing the photographic world through your pages gone, and all owing to the fertile ingenuity of friend B. J. Edwards! If I still cast a lingering look of esteem at my poor portable bantling—there it is; roomy, running on wheels, capable of carrying camera, chemicals, grub, great-coat, and umbrella, and "up" to any sized plate—it is because I know it has still virtues which tho "Graphogenic" lacks.

1st. Shelter from wind, rain, dust, and smuts when coating the plate with collodion.

2nd. Certain advantages in manipulating, which will occur to every photographer.

3rd. Not paying 60s. and upwards—and very much upwards, too—for B. J. E.'s fancy for patenting ideas; to say nothing of the expense of annually renewing the india-rubber bath.

Even as I write, Mr. Editor, my esteem for my pot portable photographic production increases. I have a few ideas left, which I shall devote to its improvement; and, while others "Graphogenicate," I shall hold fast to that which is good, and remain, your obedient servant,

INGENIO.

ANOTHER PRESERVATIVE FOR SENSITIVE PAPER;

DEAR SIR,—I think that I can name another agent which promises to be a help in photography. It has been, I believe, made use of before, but not in the direction I am about to quote; you yourself can prove or disprove the statement I make with very little trouble. Take a piece of sensitized printing paper from the bath, well wash in some changes of water to eliminate the free nitrate, and float or immerse in a solution of Calvert's pure carbolic acid, a few drops in half pint of water, hang it up to dry, and print as usual; it will print to a good deep shade, and tone, after washing, to a good colour. As to the keeping properties I can say nothing, as I have not tested in that direction, but I think I can say that, arguing from washed paper keeping better than unwashed, it will be found to preserve the whites some time, carbolic acid, I imagine, rather improving such a quality than otherwise. I also suggest its trial with your collodio-chloride, minus free nitrate.—I am, dear sir, yours truly,

Egham, April 24th, 1871.

WM. BARTHOLOMEW.

PS.—Since sending the above, I think it better to use a stronger solution of carbolic acid than that I mentioned in my letter on Monday, for I find the vigour of the print increases in a direct ratio to the strength of the solution, and that in all probability a very weak sensitizing bath is sufficient. I hope some of your amateur readers who have time will prosecute a search with this agent, and that the effect of it on the dried collodion plate may be tested in various ways, with and without another organic substance.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

A SPECIAL general meeting of this Society was held in the Hall of the Society of Arts, 117, George Street, Edinburgh, on Thursday, the 20th inst., to take into consideration suggestions from

the council for winding up the affairs of the society. The council recommended: 1st, that the Society be now dissolved; 2nd, that Mr. Fox Talbot be requested to sit for his portrait, to be presented by the society to the National Gallery of Scotland; 3rd, that a picture be purchased with the remainder of the funds, to be also presented to the National Gallery.

The Rev. D. T. R. DRUMMOND, vice-president, occupied the chair. The minutes of the last general meeting of the society, held in 1867, having been read and approved of, also the minutes of the last council meeting, the principal part of the business of which is contained in the above recommendations, the Chairman said he should be glad to hear any gentleman's opinions upon the recommendations which had come from the council to this meeting.

Mr. KINNEAR formally moved the adoption of the recommendations of the council, which was seconded by Mr. HARRIS.

Mr. BROWN said that he did not think he could give his adhesion altogether to the recommendations of the council. He regretted very much that he was not present at the council's meeting through unavoidable absence from town. He thought that the proposition to present the portrait of Mr. Fox Talbot to the National Gallery was a very fitting tribute to one who had conferred such great benefits upon the world by the discovery of his beautiful calotype process. By so doing he thought the society would be acting in conformity with the spirit and object for which the society was instituted. This would only absorb a small portion of the society's funds, but he was not sure of devoting the large surplus to the purchase of a picture to be presented to the National Gallery. This in no way could be construed as a legitimate mode of disposing of the funds of a society which were contributed for the furthering and promoting the advancement of the photographic art. Both the Royal Academy and the trustees of the National Gallery had ample funds at their disposal to give encouragement and to carry out the objects for which they are constituted; and he thought there would be no difficulty in finding a mode or manner of applying the funds at their disposal in a way that would more truly and faithfully carry out the object of the constitution of this society, viz., its direct application to the advancement of photography, either by annual exhibition, or by medals or money annual prizes to original discoverers. In some such way the spirit and objects of the society could be carried out; but he had very great objections to the purchase of the picture, either painted or to be painted, to be presented to the National Gallery.

Mr. ARCHISON thought that Mr. Kinnear's resolution, or rather the council's, was putting the cart before the horse; first dissolving the society, and then its scattered elements reuniting again, and disposing of its funds. He thought, in the first place, that before dissolution, we should make up our minds as to how we should dispose of the funds, as there is evidently a diversity of opinion amongst us as to their application. He might say at once that he had a decided objection to the picture-buying proposal. He thought a good deal might be said in favour of a portrait of Mr. Fox Talbot, but a still better mode of application of the funds would be the establishment of a modest bursary to some struggling student who was more directly pursuing the investigation of the chemical or optical sciences, as they may more immediately bear upon photography.

Mr. YOUNG remarked that he had very great sympathy with what had been said both by Mr. Brown and Mr. Archison. He thought it lay far out of the Photographic Society's way to squander its funds in the buying of a picture to be presented to the National Gallery. The obtaining of a portrait of Mr. Fox Talbot was a very happy recommendation, and every photographer throughout the world will hail with great pleasure the obtaining of a national memento of one who stands second to none amongst the original discoverers of our art; but he had a decided objection to either paint or brush being used in the delineation of those noble features. If a portrait is to be presented to the National Gallery, or, perhaps, more appropriately, to the National Industrial Museum, delineated by the pencil of light, which he had most marvellously used for the delineation of all that is true and beautiful in nature, he wished not only to see the portrait of Mr. Fox Talbot, but also those of Daguerro, the two Nioces, Le Groy, Archer, Reid, Ponton, and many others who were the pioneers of the art, presented to our National Gallery or Industrial Museum, but duplicates also sent to the galleries or museums of London, Dublin, and Paris; and this could be very easily

accomplished. We have got over all the difficulties in the want of permanency; we have the pure photograph permanently burnt in upon enamel tablets defying the ravages of time. Canvas and wood panels would moulder into dust, when the enamel tablets will remain as perfect as when they passed through the furnace. By applying part of our funds we would not only be securing a perpetual memorial of these men, but we would be stamping, by our appreciation, the highest development of photography; for, in his humble opinion, every kind of photograph dims before a beautiful enamel, and it would be a tribute to two men who have done more than all others in developing this most beautiful branch of our art—Lafon de Camarsac, of Paris, and Hendersou, of London. Then with regard to the residue of our funds, he would have an annual, biennial, or triennial money prize for any new discovery that may be made in any given year, which a committee might think of sufficient merit; but not a sixpence should be applied in any way but for the advancement of photography.

Mr. WALKER did not think, with Mr. Tunny, that an enamel would at all be compared to a fine large oil painting; everybody could see it, while an enamel had to be looked for. He thought that the very best application of the funds was that proposed, the painting of a portrait, and the buying of a picture.

Mr. McNAIR thought that some way of applying the funds as indicated by Mr. Tunny would be much more consonant with the spirit of the constitution of our society. He did not think the applying of our funds to the purchase of a picture at all right.

Mr. T. B. JOHNSTON said he might mention the fact that the great difficulties he had, when secretary, of getting up original papers to interest the members, convinced him that there would be no hope of getting a committee to interest themselves sufficiently to take charge of the annual awards as proposed, and he did not believe that the National Gallery would receive the enamel portraits.

Mr. TUNNY said if the funds were to be broken into fragments, he thought they could not do better than allocate £50 for the purpose of assisting to defray the expenses of a National Photographic Exhibition, to be opened during the meetings of the British Association here in August next. The Edinburgh Photographic Society, he had no doubt, would gladly take the trouble, and manage the whole business of the exhibition.

The CHAIRMAN said that if it had not been for the remarks Mr. Tunny had made, he would not have mentioned the fact that he had received a note from one of the council of the Edinburgh Society, making a similar suggestion. He thought good might come of such an exhibition.

Mr. SCOTT ELLIOT said it was Mr. Johnston's belief that the National Gallery would not receive photographic portraits; and, if they have such little appreciation of photography, why should we offer to decorate the walls with our funds? If a portrait was to be presented, he would prefer that of Mr. Scott Archer, who, he considered, had done more for photography than any other man.

After considerable and prolonged discussion, it was ultimately agreed, on the motion of Mr. Brown, "That the Society be dissolved after another general meeting had been called on the 22nd May, the funds disposed of, and all the other business of the society wound up." This was seconded by Mr. ARCHISON.

A vote of thanks to the Chairman terminated the proceedings.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Association was held at the Free Library, on Tuesday, the 25th inst., the President, Mr. THOMAS HIGGIN, in the chair.

The SECRETARY read the minutes of the previous meeting, were passed.

Mr. E. ROBERTS exhibited some beautiful stereoscopic transparencies, taken by the coffee process, using some of the coffee prepared for breakfast, and put aside until the evening. The transparencies were of good colour, requiring no gold toning, and were without a spot or stain. He was not equally successful with negatives by the same process; they developed well up to a certain point, and then suddenly became covered with a muddy deposit.

The PRESIDENT suggested that for negatives a different collodion might be found more suitable.

The SECRETARY exhibited some prints mounted under thick glass, as supplied by Mr. J. A. Forrest; some cameo prints

with a glazed surface of plain collodion and gelatine; and a tissue negative for carbon or silver printing, made by taking the film from the glass after coating with India-rubber and plain collodion.

The PRESIDENT exhibited one of a series of prints which he intended taking of the fossils in the Museum; he also showed two photographs of the late eclipse taken by Mr. A. Brothers, which had been sent by Mr. Guyton for exhibition to the members. He (the President) read several extracts from the *English Mechanic*, describing the manner they were taken, &c.

Mr. R. C. Johnson then gave interesting explanations of the photographs, giving the reasons by which it was now proved that the corona belongs to the sun. A discussion followed as to the best process to be used on similar occasion, the wet collodion positive gaining the most favour.

The paper of the evening was then read by Mr. John Henderson, the subject being "Photography and the Stereoscope," which will appear in our next; after which Mr. Henderson gave some practical illustrations of the manner in which he cut his prints for mounting. He also showed several combinations of coloured glasses and papers in the stereoscope, and some stereographs in which the proper effect could only be seen by looking through the stereoscope held in a position corresponding to that of the camera when the view was taken.

After an interesting discussion, a vote of thanks was given to Mr. Henderson, and a hearty wish was expressed that he might have a pleasant trip during his visit to America, Mr. Henderson being about to spend a short time in the United States.

The meeting was shortly afterwards adjourned.

Talk in the Studio.

SOIREE AT THE ROYAL SOCIETY.—The second soiree of the season, and last one at which Sir Edward Sabine will preside, was held on Saturday last. The rooms at Burlington House were almost inconveniently filled, so numerous were the company at a later period of the evening; and the unusual interest of many of the objects exhibited caused frequent blocks in the spacious suite of apartments. Captain Monreiff's model of his barrette gun-carriage formed one of the principal centres of attraction, the ingenuity of which far exceeds, apparently, its practical value, seeing that, notwithstanding the lapse of two years since its adoption by Government, not one single example of the carriage is as yet in the service. The telegraph instruments used in the Post Office, of which there are some half dozen different kinds, formed an interesting collection; and a new description of spectroscope, consisting of but two prisms, by Mr. Browning, was also shown. An electric pyrometer, or measurer of heat, and a beautiful display of Geissler tubes by Mr. Ladd, were exhibited. Of particular interest to photographers were some of Rutherford's magnificent photographs of the moon enlarged to an immense size, and exceedingly rich in detail; a series of large pictures of Japan, measuring some twenty inches by fifteen, shown by Captain Maddison, several of which—of Nagasaki, for instance—were very fine indeed; some photographs of recent explosions by gun-cotton at Dymchurch and elsewhere, exhibited by Lieut. Abney, R.E., who showed also his new instrument for ascertaining readily any degree of elevation; photographs of military subjects by the General Photographic Establishment at Woolwich; and also some studies by Col. Stuart Wortley. Specimens of an improved lithographic (or autographic) process were shown by Mr. Maclure, the examples being all of them very fine and tasteful; and a life-sized painting of Faraday, evidently taken from some of the characteristic photographic portraits that exist of this philosopher, was also exhibited.

PRESSES FOR COME VIGNETTES.—Referring to an answer to a correspondent in our last, Mr. Solomon informs us that he also supplies the necessary appliances for producing the cameo vignettes.

AN IMPORTANT PHOTO-PRINTING PROCESS.—C. J. Carlemann, photographer, in Stockholm, Sweden, has succeeded, after many years of experimenting, in producing, by optical and chemical means, printing plates which can be printed in the printing press simultaneously with the text, and which will furnish impressions similar to the best wood-cuts. This im-

portant invention does not aim so much at the copying of engravings and letters, but its main purpose is to furnish representations from nature with all the details of light and shadow. The inventor is at present occupied in issuing a pamphlet explaining his invention, and intends to take out patents for it in England, Germany, the United States, &c.—*Licht*.

PHOTOGRAPHS OF THE DEAD.—At the Hotel de Ville (writes the Paris Correspondent of the *Telegraph*), there is an exhibition the like of which was probably never seen before. Here it is that all particulars may be obtained of those who have been killed or wounded during the different engagements. In the long corridors you meet everywhere, waudering purposelessly, with handkerchiefs to eyes, the female relatives of the fallen. But not even this sight brings home the horror of the struggle so forcibly as another that meets your eyes. There is a series of photographs—photographs of the dead whom no one has yet recognized. Side by side with these are the number of the regiment to which the dead belonged, and that of the coffin in which their remains have been enclosed.

ROYAL POLYTECHNIC INSTITUTION.—Some very fine photographic transparencies, illustrative of glacier scenery, are shown at this institution in a lecture by Mr. Pepper on "Snow, Ice, and Glaciers." They are enlarged to a magnificent size, and thrown upon the screen in the large hall, so that their full beauty and detail are at once brought out. It is, indeed, only in this way that the actual value of photographs of grand bits of mountain scenery and gigantic waterfalls can be truly appreciated, for the diminutive views we generally see fail frequently to convey to our minds the wonderful proportions of the original scene. The views serve to illustrate very clearly Mr. Pepper's interesting remarks upon the formation and movement of glaciers, and carry conviction at once to the mind of the audience. Another entertainment not to be omitted by visitors, and especially by those interested in photography, is Mr. George Grossmith, Junr.'s, amusing recital; a very instructive lesson may be taken of this gentleman on "How not to do it," in portraiture. Mr. Grossmith seizes upon half-a-dozen of the most hackneyed poses to be met with in all photographic albums, and these he depicts so cleverly and funnily, and, withal, so truthfully, that the audience are made to laugh again over their own weaknesses. Some capital songs of his own composing conclude the entertainment. Other amusements, too numerous for mention here, fill up an agreeable evening at the Polytechnic.

ANOTHER CONVICTION FOR SELLING INDECENT PHOTOGRAPHS.—Claud Boosoli, 53, was indicted at the Middlesex Sessions, April 25, for selling and uttering two low and obscene photographs. The prisoner pleaded guilty. Mr. Besley, who appeared for the prosecution, said that, in consequence of complaints made of the prisoner's dealing in grossly indecent photographs, the authorities of Scotland Yard instructed Inspector Denescoutch and Detective-Sergeant Greenham to take such steps as they might consider to be necessary for the purpose of testing the truth of the complaints which had been made. Accordingly, Sergeant Greenham went to the prisoner's house at 84, King's Road, Chelsea, and had his photographic likeness taken by the prisoner. Some conversation afterwards took place between them, and at a subsequent interview the photographs were sold at 2s. each. A warrant was issued, and on the prisoner, at the studio, and at his lodging, photographs and negatives of the same description were found. Mr. Collins, who appeared for the prisoner, urged in mitigation of punishment that the sale was made after solicitation by the officer, and at a very small price, which showed that the prisoner was not a systematic dealer. The judge said it was almost impossible to realise the demoralizing effect of such publications upon the young, and the Court, refraining from passing the full punishment the law allowed, must still inflict a severe sentence, which was, that the prisoner be imprisoned and kept to hard labour for twelve months.

MORE PIRACY.—A few days ago, at Worship Street, George W. Knight, a picture frame maker and photograph dealer, of Tabernacle Walk, Finchbury, attended in answer to a summons which charged him with having unlawfully and knowingly sold a pirated copy of a registered photograph of the Oxford crew, 1871, contrary to the 6th section of the Copyright Act. Mr. George Lewis appeared in support of the summons; the defendant was not represented. The complainant was Mr. Henry William Taunt, photographer, of the Corn Market, Oxford. He deposed that the Oxford crew sat to him for a grouping picture,

which he registered and published. He took six plates of the crew, and had not allowed either of the negatives to go out of his possession. The defendant, in answer to the charge, denied that he knew the photograph was a protected one. He said that he had purchased it in the street from a lad named Conroy, whom he called as a witness, but the lad could not say if the photograph produced was the same purchased from him. Mr. Lewis said that the defendant had previously been convicted of a similar offence, and fined £25. The full penalty for every false copy was £10. The magistrate inflicted a fine of £5, with the alternative of two months' imprisonment with hard labour. The money was paid.

SENSITIVENESS FOR LIGHT OF THE HALOID SALTS OF SILVER, AND ON THE CONNECTION EXISTING BETWEEN OPTICAL AND CHEMICAL ABSORPTION OF LIGHT.—C. Schultz-Sellack, in a paper contributed to the Berlin Chemical Society, states, as the results of his researches:—"All rays of coloured light which are optically perceptibly absorbed by the haloid salts of silver in films of some few millimetres' thickness cause a chemical decomposition. The absorption of light is in these substances always connected with chemical action. All the haloid compounds of silver are chemically affected and altered by all those rays of light which the salts absorb in perceptible quantity."

THE BROMIDE PATENT IN AMERICA.—The sometime holders of this iniquitous patent are singularly persistent. Having been more than once defeated in their efforts to get it renewed after its original term had expired, a fresh effort has recently been made to establish the impost by another application to the Senate. Fortunately for our American brethren, the application was not successful.

LORD BROUGHAM AND PHOTOGRAPHY.—In the recently published *Life of Lord Brougham* it is remarked:—"At sixteen Brougham wrote an essay on the 'Refraction of Light,' and had already hit on the 'Binomial Theorem,' made additions to the Newtonian doctrine on light and colours, and discovered *Photography*. Brougham sent a paper to be read at the Royal Society; certain parts were omitted. 'This was very unfortunate,' he says, 'because I, having observed the effect of a small hole in the window shutter of a darkened room, when a view is formed on white paper of the external objects, I had suggested that if the view is formed, not on paper, but on ivory rubbed with nitrate of silver, the picture would become permanent.'" His Lordship seems to have overlooked the fact that Wedgwood and Davy produced images by the action of light on salts of silver; but it was not until the discovery of fixing agents, many years later, that permanent pictures could be produced.

CAUTION AGAINST INSUFFICIENT WASHING OF THE NEGATIVE.—It sometimes happens that landscape negatives which are taken in very warm weather with the wet process will, on the return home, be covered with an effervescence or small star-shaped crystals. The cause is insufficient washing after development. The margin of the plate should be brushed over with some negative varnish. When this has dried, the plate is immersed for some time in an old silver bath, which will dissolve the crystals, and the clean plate is now ready for fixing. These last operations must be carried on in the dark room.—*Archiv.*

BLUE FROSTING FOR SKYLIGHTS.—As it is sometimes desirable, particularly in winter-time, to have colourless panes, in place of the blue glass of the glass-house, I use the following colouring solution for my skylight. I make a saturated solution of Glauber's salts in beer, and add Prussian blue until the desired depth of colour has been reached. This mixture is placed on the glass while warm. When cool it is crystallized. It can readily be removed with a wet sponge.—*Archiv.*

To Correspondents.

B. T.—If a toning bath of chloride of gold and acetate of soda be made of the proper strength for use, and used carefully, so as to avoid contaminating it, it may be kept in the dark a long time without deterioration or precipitation. When we used an acetate bath we kept it for many months, using it over and over, merely adding to it, as it diminished in bulk, a fresh supply of new solution of the proper strength. This plan answered perfectly.

MIDDLESEX.—You will see from a letter in our last that albums for the Victoria cards are already in existence, and that the necessity for importing them, therefore, no longer exists.

KELSO.—The damaged glass, which you describe as "mildewed," may possibly be improved by rubbing the surface with putty powder, which will polish off the injured surface. 2. Tunicare answers well so far as we have general testimony.

F. C. S.—We do not remember any special paper or article on photographing interiors with dry plates, although there are many scattered hints on photographing interiors. Unless the church interior is much lighter than churches usually are, dry plates are not often used for such a purpose, on account of the enormous exposure which would be required. If, however, you wish to use a dry process, try that with which you are most familiar, and use as large a stop as you can without sacrificing definition.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.—Mr. Hubbard, to thank Mr. Foster and ourselves for explaining that the Committee rejected the pictures for want of novelty, says:—"I cannot complain, nor should I on those grounds, if they had not accepted one. I did not feel disappointed at having one returned, for that I expected. It was my surprise in having the one that I placed the greatest confidence in, that if any were retained it would be that. I was sorry I had nothing new to send, but there was no chance with such a winter as we had in London. I think it would have been wiser if the Committee had made known to photographers, through the *News*, their reasons for rejection, thereby laying at rest many perplexing thoughts." Our correspondent should bear in mind that the Committee could scarcely be expected to explain that which, in their estimation, should have been self-evident—namely, the importance of novelty. It is scarcely customary, either, for a body of gentlemen performing a public duty to voluntarily place itself on its defence on indefinite charges. We sought the explanation from the Committee in the interests of photographers, and made it known as soon as possible after visiting the Exhibition.

GENUS.—There are various methods of obtaining a suitable surface in the negative for retouching. More than one kind of varnish is in the market, the object of which is to give a matt surface suitable for retouching. The ordinary negative, if used somewhat dilute, and with very little heat, dries sufficiently matt to permit retouching. Some photographers apply a little cuttle fish or pumice-stone powder to such portions of the varnished negative as they wish to retouch, and, by rubbing slightly, remove the high polish. 2. It is somewhat a matter of taste with the artist as to whether lead pencil or water colour is best for the purpose. Where very little working is required on the negative, lead pencil is preferable. 3. Various water colours may be used; Payne's grey answers well. 4. We have published many articles on the subject of retouching, both in the *News* and *Year-Books*. You will find an article on the subject in the last edition of Newman's work on colouring photographs. The extracts from an American work we recently gave, constituted the whole of the instructions in the book.

TIBER.—Various fluxes are used in enamel work. Here is one: 12 parts powdered flint glass, 4 parts powdered flint, 3 parts calcined borax. Melt together in a Hessian crucible for some hours, then granulate by pouring into water, and finally reduce to a fine powder in a mortar. You can buy this more easily than you can make it. 2. Mr. Solomon will supply you. 3. We do not understand your question as to "means for taking pictures off enamels after having been burnt in." Do you mean taking copies of enamels? If so, proceed as in copying other pictures.

EXCELSIOR encloses us a copy of one of the letters which have appeared in the daily press suggesting a tax on photographs. He says:—"I enclose letter cut out of the *Standard* to-day, Tuesday 25th [the letter is one of those referred to in a leader]. It may or may not have come under your notice. What particularly attracted my attention was that portion of it relating to the cost attending the production of the negative. The idea of negatives costing 'little or nothing' for taking is so universal, that it appears to me quite time the public were more generally informed, not merely as to the expense of chemicals, but also the necessary plant required, together with the value of the operator's time. I, therefore, draw your attention to this, in the hope that either yourself, or some other more able hand than mine, may take the matter in hand. We photographers, especially in portraiture, are considered generally as mere machines, and beneath even the colourist, setting aside the artist; the former of whom is entirely dependent upon us, the latter becoming daily more dependent. There are the gentlemen photographers, accustomed to taking views on large plates, very beautiful and well chosen, as also well manipulated; but where is the skill required compared with the portrait photographer? It is time, I say, therefore, for some able hand to disabuse the public mind. I am looking forward to the results of the forthcoming Exhibition to do something, and, in conjunction with a clearer representation in the public press, and such a class of work from photographers themselves, to photography taking its proper position of an art science." The statement as to cost of photographs in the letter in question was too preposterous to need serious refutation.

Several Correspondents in our next.

PHOTOGRAPHS AT THE INTERNATIONAL EXHIBITION.

THE first of the projected succession of Annual International Exhibitions of works of industry and art was opened in state on Monday last by the Prince of Wales. The aim of the series of Exhibitions now inaugurated is to carry out the purposes in promoting art and industry, of the Royal Commission appointed to dispose of the surplus funds of the Exhibition of 1851. The report presented to His Royal Highness during the ceremony of Monday explained the intention and motives which have governed the Commission in the present project. In order to avoid the tendency to undue increase in size and extent, it was resolved to hold a series of smaller Exhibitions, and to confine the Exhibition of each year to two or three industries only, admitting, however, every year works of fine art, scientific invention, and horticulture; and to admit such objects only as might be selected as worthy of exhibition by a competent committee of selection. This committee of selection perform practically the work of a jury, and the certificate of admission will be, in effect, a certificate of merit. The decision of the Commissioners is not in favour of the system of prizes, which, it is stated, has proved a source of dissatisfaction, and, sometimes, of abuse. Practically, in fact, the jury system is declared to have failed. "The estimation of the merits of the goods of each country," it is remarked, "was often determined very much in the proportion of the number of the jurors it was allowed to name. It was impossible to find jurors with sufficient technical knowledge of all the subdivisions necessarily grouped under one heading to pronounce comprehensive and correct judgments on the comparative excellence of the objects exhibited. And amid the enormous mass of objects which such immense exhibitions brought together, many oversights occurred, which did injustice to individuals."

As the report proceeds to remark that "the admission to the Exhibition itself, in the opinion of your Commissioners, should be viewed as conferring a distinction worthy of competition," it practically re-establishes the functions of the jury, and it may be doubted whether entire exclusion, by the decision of a committee, from the opportunity of exhibiting, may not be regarded as a worse fate than exclusion from the awards of merit by a jury after exhibiting. There can be no doubt, however, that the public will be the gainers in the higher character of the contributions.

The official reports to be issued will aim at something more than a mere record of the contributions and their character. It is stated by the Commissioners that "in these reports an attempt will be made to inculcate such principles as will enable the public to arrive at a standard

of judgment, and form its own opinion upon them." The appointed reporter for photography is a gentleman thoroughly familiar with every branch of photography, and well able to form a due estimate of the subject entrusted to him, as all who know the work of Col. Stuart Wortley will readily admit.

Photographs, being in this Exhibition classed amongst fine arts, will be admitted every year; an arrangement which will permit the display of annual progress, novelty in subsequent Exhibitions being an absolute condition of admission.

We have before briefly noted the character of the display of photographs at the present Exhibition, and owing to its incompleteness in some respects—owing to the late arrival of some foreign contributions which are neither yet hung nor catalogued—we can now only give a general glance at the pictures. They are hung, as we before stated, in the lofty gallery which runs round the Royal Albert Hall, where are found—in company with water colour drawings—engravings, lithographs, and works of similar description. The ensemble of those already hung is effective and satisfactory, and the chief cause for regret, when examined in detail, is found in the fact that so many of them have been exhibited before. Another cause for regret in an International Exhibition is the fact that some important nationalities are altogether unrepresented. We find nothing from France, a circumstance easily understood. There is very little from Prussia, nothing from Italy, nothing from Canada, nothing from Australia, nothing from the United States, nothing from Russia. Of the states of Continental Europe, Hungary is best represented, some very charming photographs having been sent by Hungarian artists. Austria and Belgium are also well represented.

Amongst the novelties contributed by English photographers, perhaps one of the most striking is a subject-picture by Mr. F. C. Earl, of Worcester, who has been chiefly known hitherto by his noble landscapes. This is a combined photograph about eighteen inches by fourteen, entitled "In Memoriam," and represents the interior of a death chamber, lighted by a single lamp. In the centre is laid, placid in death, the figure of a young man; and leaning over him, on her knees, a young lady—wife, it may be, or sister—her back to the spectator, evidently bowed down by deep grief. The chiaroscuro of the picture, the realism of the lamp light, the softly spread illumination, which is thrown into a definitely pyramidal form by the shade over the lamp, and the quiet gloom and stillness, are admirably managed. The sharp, sculptural definition of the young man's features, seen in profile, and the perfect effortless repose of the eye-lids, suggest actual death; and the feeling of pain and solemnity which must ever be associated with the real, rather than the

pictured, presence of death steals over the beholder, which may suggest again the question, which has been discussed before, as to how far it may be permitted for the realism of photography to deal with certain actualities which are too intimately connected with the sacred things of human life. If the subject be legitimate for the photographer's art, it is here treated with admirable skill and taste; there is nothing gross in the realism; a perfectly reverential tone, and the purity of true art-treatment, pervade the whole. The fine lines of Longfellow which are appended to the picture are in perfect keeping with the suggestion of the composition—

There is no death! What seems so is transition.

This life of mortal breath
Is but a suburb of the life Elysian,
Whose portals we call death.

He is not dead—the child of our affection—
But gone unto the school
Where he no longer needs our poor protection;
And Christ Himself doth rule.

Also noticeable amongst the novelties are some fine portrait studies and character-pictures by the Hon. Ronald Leslie Melville. This gentleman is an amateur, with whose works, until now, we have not been familiar. They all display considerable artistic taste and feeling, and suggest something of the characteristics of the work of Mr. Rejlander and Mrs. Cameron. They have, however, qualities essentially their own, and the photographic execution is, moreover, good, and free from the slovenliness which often characterizes the lady's pictures. We shall have occasion to refer to these in detail hereafter.

Mr. Slingsby contributes some exceedingly fine large portraits of a similar size and character to those sent to the November exhibition of the Society, the subjects here being new and effective. Mr. Dismorr, of Gravesend, also sends some fine Salomonesque portraits, which have not been exhibited before. A portrait study entitled "Rosa," by Mr. F. Piercy, produced by his especial method of artistic printing, is very charming, as is also a pretty little child's head by B. Scott and Son, entitled "The Morn of Life." Mrs. Cowper, whose work we have not seen at any previous exhibition, has some exceedingly fine reproductions, printed both in silver and carbon.

Prominent amongst familiar pictures are the fine seascapes and landscapes of Messrs. Robinson and Cherrill, and the "Trysting Tree" and "Over the Sea" of the same artists; the noble portraits by Mr. Blanchard; studies by Mr. Rejlander, Mr. Hubbard, Mr. Warwick Brooke, Mr. A. Diston, and others; the charming studies of children by Mr. Faulkner and Mr. Heath; portraits by Mr. Ashdown, Mr. Briggs, Mr. Beau, Stereoscopic Company, Mrs. Cameron, Fradelle, and others; landscapes by Mr. England, Mr. Earl, Captain Lyon, Mr. Brook, Mr. Godbold, Mr. Beasley, and others.

Permanent and photo-mechanical printing processes are well but not numerously represented. The Autotype Company have a magnificent display of specimens. Mr. Woodbury has some very capital examples. Messrs. Edwards and Kidd send a good display of heliotypes. Mr. Henderson sends some fine enamels.

The foreign contributions include some very fine pictures, to which we shall refer when all are hung.

PHOTOGRAPHIC PORTRAITURE IN INDIA.

We subjoin some extracts of a letter from a portraitist in India written to a friend in this country; many of the observations will interest our readers:—

"The common plan of taking portraits out here is simply to place the sitter under cover (shelter over his head) in the open. Of course, the best time for that sort of work is about 8 a.m. It is a capital plan for children. In fact, I find it so good that I have fitted up a contrivance of the sort outside the studio, and can take babies in three

seconds with No. 2 stop with ease. At this time of the morning the light is soft, and I arrange that it should come on to the sitter as nearly as possible like in the studio: shade on one side, light on the other.

"Talking about studios, I may as well say that I got a wrinkle from the one I worked in before, which is, that I feel convinced that in building a studio have plenty of light in the side light. The one I had before was about 12 feet to the eaves, whereas mine here is not more than eight. This was false economy. What do you say; you who have built so many? If I have time, I will enclose the different elevations for you to see what it is like. As to working, I cannot complain. I give twenty seconds for a largish vignetted head (C.D.V. size), with No. 2 stop, cloudless sky; twelve to fifteen seconds standing figure.

"Now let me say a few words upon photographic subjects. First and foremost comes Robinson's luxurious and delightful process the "Syrup." What a treat it is to go into the field feeling the utmost confidence in working it! When compared with the old plan of fixing in the field, is the word "luxurious" misapplied? I constantly go out many miles, sometimes away from the studio, to take bungalows, horses, and groups on 12 by 10 plates, and *always* work the "preservative." I have no more hesitation in applying it to a plate of a large group than I have to a landscape, and *never* have I failed; not a stain is to be seen on the plate. "Golden syrup" is dear here, so I have recourse to the commonest treacle—

Treacle	4 ounces
Water	6 "
M. spirit	1 ounce

The same as I put in the same quantity of developer. This solution leaves nothing to be desired.

It is an invaluable process, and, knowing it to be such, I have made others acquainted with it here. What a comfort it is in the field, is it not? What a lot of negatives one can take in half the time that would be required when fixing in the field! With regard to permanganate of potash for discolouring the printing bath, I find this also another delightful process to use instead of kaolin. I have had my doubts as to whether or not the print produced from a bath so treated were equal to others, and have often condemned it, fancying it imparted a redder tone, or that the whites were affected, it is so natural to lay the blame when anything is a little wrong, to any new process one may be experimenting with. But the comfort derived from using permanganate, not to speak of the gain derived from having no necessity to filter the solution, made me go back to it again and again. After many trials, printing the same prints from paper excited in a bath discoloured with permanganate, and one with kaolin, I have come to the conclusion that there is no appreciable difference. I use a ten-grain solution, one drop of which effectually clears a bath containing about forty ounces (in bulk). I am not aware of your method of discolouring the bath, and should like to know it. I believe a ten-grain solution of salt answers the same purpose. I intend to try that. I have been practising the "mezzo-tint" dodge also, and have succeeded in producing some beautiful results. The mechanical part of the operation is easy enough. I simply get a common packing case large enough to take a printing frame or two, place it in the open, when the sun is shining, in such a manner that none of the four sides casts a shadow on the bottom, fix it in this position by a brick or piece of wood underneath, and I or the printer stands by to see that no shadow impinges on the bottom. This is easily done by tilting or lowering, &c. About noon is perhaps the best time, the sun being then more stationary. You will see two of my specimens in this style at the South Kensington Exhibition. As I said before, the mechanical part is easy enough; there is no need of black living, and all that; the difficulty lies in knowing that you have a paper that will stand sun printing, or, rather, in knowing how a paper ought to be excited for such printing. From some papers I have found

it impossible to get a good print in the sun from negatives which have given me faultless prints from other samples. The density of the negative has, perhaps, something to do with it, but I think the paper has most.

By-the-bye, what are the requisites for direct sun printing? I am sparing no pains in finding this out, for the results from this process are charming. Glass is the best medium, I believe, as thin as it can be got. I was tempted to try this process from having taken the portrait of a very pretty lady very much freckled. She remarked that all her portraits give her such hideous freckles. I replied that she should see none in the one I was about to give her, at the same time showing her the freckles strongly marked in the negative. I was relying upon touching them out with a pencil. When I came to undertake the task, I found it would be only partially successful, and so bethought me of the "medium" printing. At it I went, and was delighted to present her the next day with a beautiful picture, not a freckle on the face, and as soft and round as possible. That lady is the one represented in the portrait with her chin on her hand. You will see that her fairness has been duly preserved."

ON HÆMATOXYLIN, AND ITS USE IN THE DRY PLATE PROCESS.

BY FRITZ HAUGK.*

HÆMATOXYLIN, which receives extensive employment among dyers, is prepared from ordinary logwood. It forms little crystalline needles, ranging in colour from a straw yellow to that of a chocolate brown, which dissolve easily in boiling water, ether, and alcohol. Erdmann and Hesse found that hæmatoxylin exerted a reducing action upon silver, and for this reason Professor von Babo suggested its possible employment in photography. Acting upon this suggestion, Dr. C. Tabensky instituted certain experiments with the compound, the results of which were communicated to the *Zeitschrift für Chemie* as follows:—

"Two plates were prepared in identically the same manner, exposed to light, and then treated, the one with pyrogallic acid solution, and the other with a mixture of hæmatoxylin; in the latter case, the picture was quite as clean and distinct as when pyrogallic acid had been used."

The formula used by Dr. Tabensky in making up his developer was as follows:—

Hæmatoxylin	1 part
Distilled water	160 parts
Acetic acid (33°)	44 "

I have repeated the experiments of this gentleman, and am able to confirm his results, but, at the same time, I hesitate to recommend the use of hæmatoxylin for the development of wet plates. With dry plates, however, the matter is different, for in this direction the compound gives surprisingly good results; and for this reason I would recommend all photographers who occupy themselves with dry plate manipulation to institute a few experiments with a hæmatoxylin developer. My own experience leads me to value the latter much more highly than the alkaline developing solutions, which, when properly employed, possess so many valuable qualities. The formula of Dr. Tabensky I have modified for several reasons, preferring the employment of a developer of the proportions stated below:—

Distilled water	4 ounces
Hæmatoxylin	8 grains
Acetic acid	$\frac{1}{2}$ ounce

Sometimes, when an inferior description of acetic acid is used, a tendency to fog is apparent upon the application of the developer, and in this case a further addition of some ten or twelve drops of the acid should be made.

The silver solution I employ is made up in the proportion

* *Licht.*

of thirty parts of water to one of silver, and I intensify with pyrogallic and citric acid.

With coffee-morphia plates, I have been enabled to obtain thoroughly exposed landscape pictures in eight seconds; by using the hæmatoxylin developer, and quicker results even I have secured with some dry plates of my own, regarding which I will say a few words on a future occasion.

A NOVEL APPLICATION OF COLLODION.

At a recent meeting of the Berlin Society, some details were given of a curious quality possessed by collodion, which has been recently discovered by M. Kleffel, and which may, it is thought, possibly lead to some useful application. He has found that if a glass plate is coated with collodion in the ordinary manner, and, after the liquid has set, a printed sheet of paper is pressed upon the surface lightly with the ball of the hand, a very exact reproduction of the printed matter will be found impressed upon the collodion after the removal of the paper, the design or type remaining perfectly visible after the complete desiccation of the film.

Particularly distinct is the printed matter when the plate is held up as a transparency, or when seen by reflected light, after the surface has been breathed upon, the type or design being somewhat sunken and bright, while the remaining portion of the film appears dull and matt.

M. Kleffel is not yet prepared to offer an explanation of this singular phenomenon, but, in all probability, the greasy nature of the printer's ink prevents its being attacked by the alcohol and ether of the half-set collodion, while the remainder of the paper is completely impregnated and softened by these volatile liquids. For this reason it is that the printing has the appearance of a *has-relief*.

To obtain the result in a perfect manner, it is necessary to employ a somewhat thick, structureless collodion, and not to allow the action of setting to go too far. Moreover, a light, even pressure is requisite to yield sharp and distinct reproductions. As a ready method of copying valuable originals, it is suggested the process might be available; then the necessary manipulations require no more time than the process of copying a written document in the ordinary copying-press.

AGAIN THE QUESTION OF WHITE OR RED LIGHT IN PHOTOGRAPHY.

BY A. DE CONSTANT.*

At the September meeting of the German Photographic Society in New York, a discussion arose on the subject of my remarks relative to whitening the walls of the camera. On this occasion M. Schène, one of the members of the Society, explained that he had made trial of this modification, and found the action of the same to be *nil*. Such a statement as this startled me very much, for the influence of the white interior, either as regards hastening the result, or softening the shadows, is so very marked, that it would seem impossible almost for the same to escape observation in experiments conducted in anything like a careful manner. So important, indeed, was the action, that I was actually compelled to give up the employment of white fittings in the camera altogether, as I found the head of the model lost its plasticity, and the picture became too flat, defects not remedied by the quicker action of the light. Inasmuch as I ascribed these defects to the strong reflection of the light rays which are thrown by the white walls direct upon the sensitive film, I am not in any way astonished to hear that M. Schène has obtained results of a similar character by means of a white cloth placed in front of the model; in the latter case, direct reflections are formed which operate in the well known vigorous manner of all white surfaces.

Anyway, this latter method of softening the shadows is not a new one. I have myself employed it frequently to

* *Photographisches Archiv.*

dissipate the shadows given by a very long nose or too prominent chin; but, at the same time, I think it well, as a rule, to avoid a bottom light, seeing that it interferes so much with the relief of the image.

After abandoning white light and white fittings, I employed red reflecting surfaces in the camera, and found therein a positive advantage, the best tint being that of a delicate rose, without mixture of violet. The direct reflections had disappeared; a sufficient acceleration was apparent, and the relief and vitality of expression were visibly improved. Since then, as I have already stated in the *Archiv*, I have found considerable advantage in the employment of an arrangement for portraiture in which the camera walls are left black, while the rosy reflection is brought about in the studio itself. By operating in this manner, the camera merely reproduces, with its customary accuracy, a soft and harmonious effect of lighting which already exists. It is the satisfactory results afforded me in practice by this method of proceeding that has caused me to recur to the subject.

My studio is of the ordinary shape, and glazed throughout, with the exception of that end against which the model is placed. The material I employ for imparting to the light its warm appearance is English muslin, moderately transparent, such as ladies employ for ball dresses, and possessing a delicate rosy hue. When I first arranged this stuff in the vicinity of the model, I found that the white light in the remainder of the studio interfered considerably with the rose-tinted light, and the clearness of the picture suffered in consequence. Upon this I fitted up the whole of the studio with red curtains, placing under the glass roof two sliding frames, to which the rose-coloured muslin was attached. The whole of the light being now coloured, exhibited a very agreeable harmony. The closed end of the studio was, when necessary, also provided with a screen of like colour, for the purpose of brightening the shadows.

The camera itself stands in a darkened space opening into the studio, an arrangement which cannot be too strongly recommended.

If the muslin has been selected of the right description of tint, the light of the studio is excessively soft, and the repose and rest to the eye so favourable, that even the weakest sight feels relief, and becomes full of that life and vivacity which contribute so much to a good likeness. When the red reflections are so strong that the object to be reproduced appears coated with colour, this is a sign that the shade of the tint is too deep. The muslin must be of quite a light and delicate colour.

Before, I suffered much in my studio from the unfavourable influence of some large white houses opposite, which, despite curtains of all kinds, always caused me much annoyance, and prevented my operating in sunshiny weather, besides causing other annoyances. Now, I am able, by means of a couple of frames stretched with rose-coloured tissue paper (muslin is too transparent for this purpose), to hinder altogether the presence of white reflections, and at any time of day, and even in the brightest sunshine, I invariably enjoy the most excellent light. To photographers, therefore, who find themselves in any way inconvenienced by the presence of white houses in the vicinity of their studios, I cannot advise the adoption of this expedient too warmly.

But I must not forget to mention the advantages to the model of this method of lighting.

In the first place, as I have already said, this description of light is exceedingly pleasant to the sitter, and the latter will not, therefore, lose his natural expression, as is the case when surrounded by a glaring white light. Under the influence of this warm harmonious illumination, the light side of the portrait retains all its fineness and half-tints to the most delicate degree, while the shadows, the hair, &c., lighted up by the rosy light, become quite transparent, and instead of the flat surfaces so frequently seen when white light is employed, all details show the highest elaboration.

This point appears to me of very great importance indeed, and leads me to the one next in order, namely, the acceleration of the photographic action, or shortening of exposure, which my method of proceeding entails.

In this respect some explanation is necessary. If, by short exposures, one understands those instantaneous landscape views without half-tone, or portraits secured in a couple of seconds, in which one cheek is represented by means of white paper, and the other by an inky stain, portraits with expressions of pain or fright, such as are produced in studios flooded with white light of the brightest description—I say, if these be understood to be short exposures, such rapidity and action must not be expected from rose-coloured light. But this modified illumination will be found to furnish a soft, harmonious portrait, full of modelling and detail, in about half the time necessary for its production in an ordinary studio, which has been so closed in, as to yield a similar result. Moreover, it must not be forgotten that an exposure of fifteen seconds in a rose-coloured light is far less trying to the sitter than a pose of three or four seconds in a blinding white light.

It is in this sense that I claim acceleration of the photographic action by means of rose-coloured illumination. The arrangement of the details of light and shade, such as the Salomon school of artistic portraiture necessitates, is more easily brought about by this means than in the ordinary way. Unfortunately, in our time, everything tends towards attaining the greatest amount of rapidity—to making things quickly and badly—and these sins one must be very careful to guard against. In my long experience as landscape photographer, I have never been able to obtain satisfactory results either in bright sunshine or by very short exposures. But I find my thoughts have caused me to wander from the subject, and I will return, therefore, to my red studio, just to say a few words upon M. Meuwssen's recent remarks upon the new mode of illumination.

I can readily believe that the red alcove or niche in which M. Meuwssen places his model approaches very nearly, as Dr. Liesegang truly says, to the Adam-Salomon system of lighting, and that the red glow furnishes portraits very similar to my own. But the front portion of the niche, it must be remembered, permits the entrance of white light, which, as stated above, interferes with the red illumination, and gives rise to difficulties which could not be overcome except by colouring the whole of the light in the studio, as I was compelled to do.

As a parting word, I may say, that after an experience of some months, I again heartily recommend this manner of illuminating the studio.

[Dr. Liesegang adds the following note to M. de Constant's communication. The pictures taken with the white camera are very soft and delicate, but not plastic; those secured with a red camera are more life-like, but, nevertheless, do not equal in clearness, transparency, and general excellence, the portraits taken in the studio illuminated with rose-coloured light.]

ON PHOTOGRAPHY IN THE PRINTING PRESS, BEING A DESCRIPTION OF THE WORKING OF THE HELIOTYPE PROCESS.

BY ERNEST EDWARDS, ESQ., B.A. (CANTAB).*

It will be well, before entering into a detailed explanation of the special process before us to night, to revert for a few minutes to the past history of photographic printing, and especially to the past history of permanent photographic printing. It is but a few years since the paintings of the sun took the world by surprise, but the wonder that they caused soon gave place to the commercial value that attached to them. Speedily a new trade, of enormous dimensions, was found to have sprung up; photographs were

* Read before the Society of Arts, April 28.

manufactured and supplied to the public by millions, and the public were satisfied so long as what they obtained appeared good. This lasted for a time, and then came a reaction. It was not long before it came to be known that, at all events in photography, the proverbial thing of beauty was by no means a joy for ever. The possessors of collections of photographs opened their portfolios to find, too often, little better than blank paper where they had last looked on treasured gems. A whisper—the forerunner of the voice which now speaks with no uncertain sound—was heard next, that silver photographs not only might, but, sooner or later, must fade, and a cry was raised for photographic printing which should admit of no reasonable doubt of permanence. Experimentalists soon produced satisfactory results in this direction, but, in the meantime, silver printing—that is to say, the process by which what we are accustomed to call photographs are produced—had established, most unfortunately, a certain standard—a standard, that is, as regards results by which all new processes were to be judged. This is what the workers in the new field have had to contend against; this is what, more than anything else, has harried their progress. No matter how beautiful the results of a new process may be; no matter that these may be proved to demonstration to be permanent, to be cheaper, to have a thousand other qualities not possessed by silver prints, and to be more artistic, the first point raised always is, Can they be mistaken for silver prints? Not are they more artistic, but, are they so like silver prints as to be mistaken for them? This method of comparison is what I protest against, for a silver print is what nothing but the fugitive salts of silver can produce. It is impossible for a silver print to be so like a drawing in black chalk as to be mistaken for it. So I conceive it is impossible for a drawing in black chalk, executed by light (which is neither more nor less than a photograph in carbon), to be so like a silver print as to be mistaken for the latter. Silver photographs are things *per se*—unlike everything else. Artists do not admire them; they are not in effect altogether pleasing, nor can any known pigment match them. Nevertheless, unfortunately for carbon printing, the standard is set up, and unless we can show a print that shall be mistaken for a silver print from the same negative, our efforts are, in many quarters, esteemed all but useless.

The ordinary method of photographic printing is based on the fact that paper treated with certain salts of silver darkens on exposure to light. If certain parts of such paper are shielded or screened from the light, these parts will remain white, and the remainder will darken and form a picture. This is what (by protecting certain parts and allowing light to act on others) the photographic negative (or shield) does. When the picture has been thus formed it requires to be fixed, to prevent the further action of light. Unfortunately, after fixation, there remain in the proof certain combinations, which of themselves contain the elements of instability, and which it is not possible entirely to eliminate, so that, sooner or later, the silver print fades.

The action which is at the bottom of nearly all the permanent photographic printing processes is that of light on gelatine in presence of a bichromate. Gelatine, or glue, which is simply a common form of gelatine, is, as is well known, readily dissolved in warm water. If we take gelatine, dissolve it in hot water, and having added to the solution some bichromate of potash, again dry it, we have a compound which is sensitive to light, but sensitive in a way entirely different to ordinary photographic paper. If we expose this compound to light, we shall find, not that it has changed colour to any marked extent, but that it is no longer soluble in hot water. If we shield a portion of the dried gelatine and bichromate from light, that portion will dissolve as readily as before, but the portion which has been acted on by light is now unaffected by the hot water. The discovery of this action was made in various steps, the first being announced by Mr. Monge Ponton as early as 1839. It is most important to keep this fundamental

principle clearly before us, for if we fail to do so, we shall fail to comprehend all that is built upon it. I may be allowed, therefore, briefly to restate it. Gelatine, or glue, is readily soluble in hot water, but if a sheet of dried gelatine containing a bichromate is exposed to light, it is found to be converted into a tough, tawny substance no longer soluble as before. This remarkable property was speedily laid hold of by experimentalists, and two groups of processes have been founded upon it. In the first group, this action is brought into play in the production of every proof. That is to say, every picture is produced by the action of light on bichromated gelatine. In the second group one picture is produced by the action of light on bichromated gelatine, and this picture is made by various devices to serve as a printing matrix, from which any number of impressions may be struck off by mechanical means.

In the first group is included what is ordinarily called carbon printing. If we take a sheet of paper prepared with a coating of bichromated gelatine, and, having exposed this to light under a negative, wash it in hot water, the portions unacted on by light will be washed away—that is to say, in those portions no gelatine will be left on the paper; but where light has acted, the water no longer dissolves the gelatine, which, therefore, is left on the paper. In other words, we have a proof, not in light and shade, but in relief and depression, some parts of the paper having gelatine left on them, others having none. Now, if previous to coating the paper we mix with the gelatine some pigment (such as carbon), and proceed as before, we shall have obtained not only a picture in relief and depression, but also in light and shade; for where gelatine is left on the paper, there will also be colour, in virtue of the carbon which is imprisoned in it; but where the gelatine is unacted on by the light, and is washed away by hot water, there the colour is also washed away, leaving the paper bare, and thus we have a carbon photograph. Herein, it is true, we have the rudiments of a process, but something more than this is wanted. A negative does not consist simply of parts where the light entirely passes through, and of parts where it is entirely obstructed. The whole beauty of a photographic negative consists in what is called half tone—that is, where the light is partly obstructed and partly passes through; and a good negative contains a thousand variations gradating in intensity from black to white. The difficulty of reproducing these was the first great obstacle to the progress of carbon printing. The action of light through such a negative on to a sheet of gelatine and bichromate is like that of cold on a sheet of water. The whole surface of the latter may be frozen over, and the ice be apparently of equal thickness throughout, but where bridges, and hanks, and trees have afforded shelter, the ice is thinner, so that though the upper surface is perfectly level, the lower surface varies with the degree of cold to which it has been exposed. So it is with the picture on gelatine. The whole of the upper surface—that surface which has been next the negative—is acted on by light, and the part that has to be washed away is underneath, between it and the paper. Directly, therefore, such a proof was put in hot water, the picture (being on the surface, and having nothing to support it) floated away, and the paper was left bare. To obviate this a very ingenious proceeding is adopted. Paper is coated with bichromated gelatine, and the carbon or pigment which is to form the picture. It is printed on by light under a negative as described; but, before being put into hot water, it is glued face downwards—that is to say, the side which has been exposed to the negative downwards on another sheet of paper. Then comes the washing with hot water. As before, the intermediate layer between the first paper and the gelatine picture is dissolved, and the first paper is left bare; but the picture itself, instead of floating away, has been glued to the second piece of paper, on which you thus have a print containing all the gradations of the negative. This,

broadly, is the basis of the present method of carbon printing. The magnificent reproductions by Brann, of Dornach, and those of the Autotype Company, are produced by such a method. It is difficult to conceive anything finer than Brann's reproductions of the paintings in the Sistine Chapel; and each one of these, and of the autotype prints, has been produced in the way indicated, and consists of a film of bichromated gelatine, having imprisoned in it any convenient colouring matter.

In the second group the gelatine picture is used as a matrix for producing a printing base, or is itself used as a printing base, which is then, in either case, printed from by mechanical means. The first successful attempts in this direction resulted in the process which is known as photo-lithography. A print is produced by the action of light on gelatine in the way first indicated. It is found that lithographic ink will adhere to those parts where light has acted. The gelatine print is accordingly inked with a lithographic transfer-ink, and the print thus produced is transferred to the surface of stone or zinc. But a lithographic stone does not do more than discriminate between black and white; it will not recognize half tone. The process is not, therefore, suitable for the production of aught else than bold work, either in dots or lines. For this purpose it is very extensively used by the Ordnance Survey Office at Southampton, by Mr. Griggs at the India Museum, and commercially in many other places.

In photo-galvanography, introduced by Herr Pretsch, of Vienna, the picture in gelatine having been obtained, a gutta-percha mould is made from it. On this an electrotype is formed, which is printed from as in copper-plate printing. Here again, as in the lithographic stone, the copper-plate does not do more than discriminate between black and white; it will not recognize half-tone, save by the conventional methods of dots and lines of greater or less degree of fineness. And it was found in practice that so much work was necessary to prepare the electrotype-plate for printing, that it became almost equivalent to an entirely new engraving. Accordingly, the process soon fell into disuse. Various improved forms of this principle have been from time to time introduced, and some are now in use—namely Mr. Dallas's photo-electric process, and, in Paris, Garnier's photo-engraving process.

Mr. Woodbury proceeds on an entirely different plan. A gelatine picture, having been obtained by light, is placed in contact with a sheet of soft metal, and submitted to heavy hydraulic pressure. Bearing in mind that the gelatine picture is a picture in relief and depression, the metal counterpart obtained by pressure will also be in reversed relief and depression. A mould will have been obtained, which it will only be necessary to fill with a solution of gelatine to obtain a duplicate, so to speak, of the gelatine picture from which the metal mould was struck. The resulting picture will be one in relief and depression; but if, as in the case of carbon printing, colouring matter is poured into the solution of gelatine used to fill the metal moulds, it will also be in light and shade. The mode of proceeding is extremely simple. A little solution of gelatine in hot water, containing suitable colouring matter, is poured into the metal mould, a piece of paper is placed on the top, and a level lid pressed down on it, so as to squeeze out superfluous gelatine. In a few minutes, the lid is opened and the paper removed, bringing with it the adhering gelatine, which, with the colouring matter, forms the picture. This is repeated indefinitely, and it remains only to fix the proof to prevent the further solution of gelatine, to possess—produced by mechanical means and independently of light—the analogue of the carbon photograph previously described. At present no pictures have been produced by the Woodburytype larger than about 11 in. by 9 in., and there is a necessity for subsequent mounting, but the cleverness and ingenuity of this beautiful process cannot be too highly spoken of.

(To be continued.)

THE "EDINBURGH REVIEW" ON PHOTOGRAPHY.*

THE Autotype process, the longest established and the best known of the different arts which have within these few years come before the public as a consequence of the want of permanency in silver prints, is the only one which can be worked by the amateur photographer, inasmuch as the whole apparatus consists of hot and cold water baths, a sheet of bichromatized and transfer paper, which may be procured from the patentees. The method of manipulation is simple enough in action, but rather too complicated to describe well, which will be the less necessary as the patentees invite the public to see the practical working of their process every Wednesday, at their establishment in Rathbone Place. It will be sufficient to state that bichromate is the chemical agent in this, as in all the allied processes, by which the most literal transcripts are obtained, not only of the most delicate silver prints, but of the artist's own work, his touch, the spirit of his brush being rendered in monochrome in the most unerring manner. We need not say, that however eminent the engraver may be, this literal translation is beyond his art. Indeed, the very eminence of an engraver is built upon a certain method of rendering effects which is peculiar to himself, and although his labours may be excellent as works of art, yet it interposes a mannerism between the artist and the public. The advantage of the Autotype, in common with the Woodburytype and Heliotype, is that it places the original picture at once before us, with the very method of the artist's touch, thus adding an immense charm and sense of truthfulness to the copy. Amid the splendid gallery of autotypes to be seen in the establishment of the Company at Rathbone Place, the great works of Michael Angelo in the Sistine Chapel are the most powerful examples. We will venture to say that before these magnificent transcripts were produced, the works of this mighty master were entirely unknown to the public, and, indeed, to artists themselves. The darkness of the chapel, the progress of age, and, as some say, the fumes of the incense, have so subdued the colour, that even the outlines of some of the upper figures, and especially those in the spandrels of the windows, are not discernible from the floor, as most visitors to the chapel must, to their regret, have discovered. This very disadvantage has proved most favourable to the autotype copies which have been successfully taken of them in monochrome—a kind of bistre, very like the tint to which the originals are reduced by the causes we have mentioned. The artist has only to compare these precious works of art with the best line engravings of the same subject to convince him how superior they are to the latter. The grand sweep of the brush of this giant in art is placed before us; the figures seem to live as they do on the walls of the building where there is light enough for the spectator to see them. The photographic negatives from which they are reproduced were taken by the aid of the lime-light, without the aid of which it would have been impossible to copy them. Another beautiful reproduction by this process is Turner's "Liber Studiormi." These sketches were painted by Turner in sepia, hence its reproduction was accomplished with facility, and with the exception of a little flatness in some of the drawings, it may be said to be a perfect fac-simile of this great artist's work. This great text-book for draughtsmen, hitherto a closed book to the public, may now be purchased at a reasonable cost. Another very charming work, the illustrations to Her Majesty's "Tour in the Highlands," by Adam, are rendered with a freshness and vigour the engraver could not approach.

It is needless to say that any drawing in chalk, Indian ink, or any monochrome, in fact, can be matched to the exact shade. Thus the artist does not lose by the translation of his work into another tone of colour. Red

* Continued from p. 185.

chalk drawings are reproduced with admirable effect. The attempt to copy in ordinary oil colour, however, presents certain difficulties, which have not yet been overcome, and possibly never will until the art of producing colours by the camera on a photographic plate is accomplished. As it is, in the initial stage, the silver print copy, certain colours, as we all know, do not respond well. Thus blue and the aniline tones come out white, whilst yellow and red print black. Thus the lights and shades of a picture painted in these colours would photograph with the balance of light entirely altered. But there are many low-toned pictures which take very well. As a rule, French pictures photograph admirably. A subdued tone is the fashion of the French school, and we may note that the canvas upon which those artists work, instead of being a yellowish-white like ours, is of a pale stone-colour. This ground, we are informed, after a time shows through and gives a prevailing grey tone, which is very favourable for taking photographic copies. In the show room of the Autotype Company there are two copies of well-known pictures—"The Arrest of Hampden when about to embark for America," by Lucy, and "The Princess Elizabeth hearing Mass," by Marcus Stone. We do not remember the balance of light in these pictures, but in the autotype copies it is admirable; but this effect has not been produced by the simple process of copying. The method is either for the artist to make an Indian ink drawing of his picture for reproduction by this process, or, if the details are too elaborate, the picture is photographed and the proof sent to the painter, who corrects any faults as to arrangement of light caused by the photographic transfer, either with his chalk or brush, and from this corrected copy the prints are reproduced. The negatives when thrown out of balance from the reason before mentioned are retouched, and a large number of artists are employed in this kind of work. Landscapes from nature require to be corrected in the negative, and the vast number of photos from popular pictures are reproduced by what may be termed this appreciative and intelligent method of translation, which can only be effected by a certain artistic skill.

The facility the autotype process offers to artists to enable them to give the public transcripts of their works cannot be looked upon as the least advantage of the discovery. The ordinary process of line engraving is denied to all but the highest class pictures; no one but a great capitalist will undertake such works. The expense is enormous, and the time consumed in their accomplishment renders the chance of their being finished in the lifetime of the artist very problematical. Raphael Morghen occupied six years in engraving the "Transfiguration;" Doo was twelve years at work in engraving the "Raising of Lazarus," and it was not finished when it passed out of the veteran engraver's hands. It is true we have no longer such great works as these demanding the labours of the engraver; but the genius we still have in the artistic world cannot fail to benefit by these newly discovered rapid means of reproducing their works. In a week after a picture has left the painter's easel, a proof impression is presented to him for correction.

But in a very large number of cases these corrections are not needed. We all know how many charming photographs, both of figures and landscapes, meet our eye in the shop windows. We feel quite sure that the majority of these have received no correction in the course of being printed, as they could not otherwise be sold so cheap. When we say that literal copies of all these, in almost any tone desired, can be given by the Autotype Company, and by the other processes we have mentioned, it will be seen how vast is the work they will be called upon to accomplish. The galleries of the Continent have already been reproduced by M. Braun, of Dornach, who holds the autotype patents for France and Belgium; and the rarest pictures of Vienna, the Louvre, and the galleries of

Florence and Venice, can be procured at the establishment of the Company at a price which is merely nominal as compared with line engravings, to which, in some cases, they are superior. The Autotype process, as far as we can see, is the best adapted of any of the allied methods for the production of the larger works of art. From this field the Woodburytype method is excluded by the comparatively small size of the hydraulic press used, and the Heliochrome method by the size of the Albion press by which its impressions are rolled off, neither of which could take the impressions as large as four feet by three, which the Autotype has just accomplished. But it must be remembered that the Autotype process is a comparatively dear method of production. Every print is accomplished by hand work, and it is not capable of reproducing with great rapidity, by mechanical means, like the other methods. For this reason it will be confined to the higher class of works, for which the comparative cost will be a minor consideration.

LITTLE DODGES.

BY C. A. WINSOR.*

I AM pleased with the disposition manifested by many of our shining lights in photography to impart so much valuable and useful knowledge as they are now doing through your deeply interesting journals. New formulas by which we can revolutionize old ones are not what we can or must expect, but nothing can work a greater revolution in the studios of *wen's* of short experience than to find so many "little dodges," as many term them, while I know, from sad experience, that many of them are very large indeed to a young operator, who would have them to work out without the assistance of others. Let them come, and, by your permission, I will add a few:—

1st. To mark stereos I fold the print together, and cut the ends of both prints at one time; then remove the pattern a little, and, with the knife, cut off just enough of the inner corner to be seen, and, when mounted, the corners go at the ends of the mount. Save time and a sure mark.

2nd. I mount all my prints wet by throwing them, face down, on a piece of glass and draining out the excess of water, arranging them so that I can paste eight or twelve at once. By no means new, but cannot be beat. Cut prints before toning, which I always do.

3rd. I make all my dishes for toning, fixing, washing, &c., by making wooden ones of $\frac{7}{8}$ by 2 to 4 in. stuff (pine), rabbeted to let the glass in $\frac{1}{2}$ in.; bed the glass in good putty, and tin it in and putty same as window glass is set; coat the wood all over with paraffine (or paint the outside), and your dish is ready for use. I have used one 20 by 24 for more than eighteen months, that has not leaked a drop. But to mend a leaky one, heat a piece of iron, and run it round the inside when perfectly dry, and it is mended. Cost of such dishes from 50c to \$1.25, according to size.

4th. I albuminize my negative glass and sell my old stocking-legs. First soak the glass in nitric acid and water. Filter a large bottle of water, also a bit of alum (white of three eggs, 60 ounces of water, and a little ammonia to keep it). I take my plates out into a pail of water, proceed to the dark room, where I have a board with nails driven in rows, and commence operations by taking a plate from the pail, washing it under the tap with my hand, rinsing it with the bottle of filtered water, and flowing it with albumen on one side only; put it on two nails to dry, top out from the wall.

I think the small amount of albumen used in this operation will not turn yellow enough to do any good; besides, the plates are reliable, seldom streak, film never slips off. It is cheaper than alcohol and rottenstone, say nothing of elbow grease.

5th. To hang frames in your display-room all over the wall with cord is no small task. They will not hang to

* *Photographic World*.

suit you, or the string of one will interfere with another, and so on. To beat such fellows I bend a wire thus, put

the ends up through the screw eyes, and hang on a nail directly behind the frame. The ends of the wire keep the top of the frame out from the wall; and this is also very cheap. Cord, if old, becomes moth-eaten, and the frames drop down, smashing things.

FOCUSING AND EXPOSING.

BY ELBERT ANDERSON.

[MR. ANDERSON proceeds with his dialogue instructions in our Philadelphia contemporary, his present lesson consisting of hints on focussing and exposing.]

A. Having now all our chemicals in order, it were well we inspected our camera. Mr. Carey Lea says:—"Any camera that is not thoroughly good, is absolutely worthless." I say Amen to that. And our mutual friend, Edward L. Wilson, says:—"In choosing your apparatus, you are told to 'get the best,' otherwise your apparatus will inevitably 'get the best' of you." In my camera I have taken the liberty of making several important alterations which, for my use, are a decided improvement. The swingback, especially, is vastly improved by placing the pivot (which is now erroneously placed in the centre of the ground glass), intermediate between the centre and the top of the box. By this change the focussing can be done in less than half the time, as when hung in the centre.

M. It is highly essential, I believe, that the ground glass and the sensitive plate, in the holder, should occupy exactly the same plane in regard to the lens. Is it not?

A. Don't be too sure of that, Mr. Marshall, or you may be led into a wilderness of trouble.

M. Why, you don't mean me to tell me that if—

A. Yes, I do mean to tell you that if—your chemical and visual foci are not "corrected," your negative will not be sharp. The focus will be either too far back, or too far front.

M. By Jove! I never could get my negatives sharp; the focus was always too far back, *back, back*. I focussed with the greatest care, and I could only get it sharp by moving the ground glass back after sharp focussing. I always imagined something was the matter with my eyes. I thought I was perhaps too far-sighted.

A. It appears you were not far-sighted (!) enough to discover the cause. I'll explain it. Take a piece of paper four or five inches long, upon which is some printed matter, in fine type, running along the whole length of the paper. Set this up in front of your camera (which must stand perfectly level) in an oblique position.

M. What do you mean by an oblique position?

A. The paper must not stand at right angles to the tube, but must be inclined slightly, so that the lettering on one side of the paper shall be nearer the camera than the other.

M. Just so.

A. With a microscope, focus as sharp as possible the centre letters, on the ground glass (which must, of course, stand perfectly true with the camera). Observe that the letters on the extremities of the paper must be slightly out of focus, the one side being too far back, whilst the other side will be too far front. Now put in your plate-holder (containing a piece of flat ground glass in lieu of the sensitive plate), and notice very particularly if the paper presents the same appearance in both instances. If not, the plate-holder

is wrong (provided always this has not been done on purpose). If, on the contrary, they both coincide, coat a plate and make a negative of the printed slip of paper. Examine the negative carefully, and if it is as sharp in the centre as the printed slip was, you are all right, for the chemical and visual foci agree. If, however, the ground glass and the plate-holder do not agree, and still the negative is sharp in the centre, this will show that the foci did not agree, and that the plate-holder has been adjusted so as to correct this difference. Finally, if the ground glass and the plate-holder do agree, and your negative is not sharp in the centre, observe where it is most sharp, either back or front of the printed slip. If back, the ground glass must be approached nearer the lens; if front, it must be set further back from the lens, and you may easily correct the difficulty yourself. Now, all being in readiness, Charley will sit.

M. How much time shall I give?

A. What a question! This will simply depend upon—first, the quality of the light; second, the quantity of the light; third, the state of the chemicals; fourth, size of diaphragm; fifth, nature of subject; sixth, nature of background.

M. Is that all? Shall I make one or two on a plate? What do you think of this sliding plate-holder arrangement?

A. Provided you make the two exposures exactly alike in position, light, &c., I think well of it; but if you change the positions and light, I consider it a perfect abortion.

M. Why, you astonish me. I always thought it a capital arrangement. What is your objection to it?

A. Let me answer (!) that question by asking you another. Coat a plate, and, before exposing it, let it stand a couple of minutes in your plate-holder; now expose and develop at once; mark that plate No. 1. Coat another plate and expose at once, but do not develop it for two or three minutes; mark that plate No. 2. Coat another plate, and expose and develop at once; mark that No. 3. Now, which do you suppose will be the best of these three, the conditions of light, subject, exposure, &c., being the same in all these instances?

M. Why, the last one, No. 3, I should think.

A. Why?

M. Because I have always been taught that the plate should be exposed as soon as properly coated, and developed with all convenient dispatch after exposure, in order to secure the best chemical effects.

A. Assuredly. But, admitting that both numbers 1 and 2 are good?

M. Then they would have been still better if they had not been subjected to this loss of time. But no one would think of taking negatives expressly, in the manner you have just stated.

A. Oh, my dear sir, you are entirely mistaken. The very fact of taking two differently lighted pictures on one plate accomplishes this very thing, and what makes the matter still worse, is in the development. For, in the first instance, should the plate have inadvertently stood too long, either before or after exposure, the development might be controlled, there being but one picture to manage; but the case is vastly different in this latter case, as one picture may be entirely over-developed before the other is sufficiently brought out, and you are just as likely to lose the best one; in any event, one of the two must needs be the sufferer. Granting, then, that neither had moved, and you save both, still you admit, under the best of circumstances, they would have been "still better" if sooner manipulated. Now suppose one has moved, you cannot, of course, tell which until after development, thus you may possibly—nay, probably—ruin the best one in trying to save the worst. Finally, you are lucky (for it is nothing but luck), and you succeed in saving the best one. You now set to work to make another negative of the other position. Pray, Mr. Marshall, what have you gained? Just nothing; on the contrary, this is a great loss of time. For had you taken both positions alike—

first, your development would have been easily accomplished; second, you would have had a double chance of securing a good picture; third, you coat another plate and have all these advantages for your second picture; fourth, and finally, experience proves that, even when both positions are alike, more time must be given for the second exposure. Consequently, when the positions and light are changed between the exposures, it required a very practiced hand to determine the time so accurately that they may doth develop together.

M. I never thought of that.

A. Naturally not; you, as the artist, have your mind on the pose and light; but go into the dark-room, and ask your operator what he thinks of it. Believe me, sir, the only advantage I see in it is when you wish to take several negatives all alike (and this must be a case of very rare occurrence), or where you take two with the hope of getting one good one.

IMMODEST PHOTOGRAPHS.*

PHOTOGRAPHY is very justly looked upon as one of the greatest blessings of modern civilization. That wonderful combination of sunlight, cyanide of potassium, and a dexterous manipulator can effect almost everything but the transfer of colours. Form and proportion we get to perfection, and nothing comes amiss as a subject, from a skeleton leaf to that cumbrous monster, the rhinoceros of the Zoological Gardens. Photography can bring into the bosom of our families the expressive lineaments of a bench of bishops or a board of guardians, a vestry meeting or an "All England Eleven," a "man of the people" or a crowned representative of the Divine right, a life-boat crew or a group of bridesmaids—in fact, anybody or anything the world is supposed to include among its choicest treasures. The familiar carte-de-visite not only perpetuates the pleasant memory of our friends, but possibly retards the process of ossification in the hearts of our enemies. More than this, the "counterfeit presentments" of photography bring us face to face with our teachers of the pulpit and the stage.

For these small mercies (especially the latter) it is to be hoped we are sufficiently grateful; but human nature is perverse, and many persons would possibly be content to see fewer portraits of our so-called actresses boldly confronting them from the shop-windows of stationers and photographers. The unsophisticated youth quietly contemplating a galaxy of stage beauty behind plate-glass, may well wonder what manner of women these can be who parade themselves and their not too voluminous costumes in the glare of day. The "chariest maid," as *Laertes* says, "is prodigal enough if she unmask her beauty to the moon." What, then, shall be said of those who confide themselves to the tender mercies of the camera when *Phœbus* is at the meridian? Is this walking into the sky-parlour of a photographer a sublime form of womanly devotion and self-denial for the good of the dramatic profession? Certainly not; and by no stretch of toleration can such a proceeding be defined as anything but a lamentable mistake, and a cruel insult to the worthier members of a profession the world is always glad to honour when it honours itself.

Photography, it is said, can never lie, or misrepresent; but it can, and does, when it gives the collective term of "favourite actresses" to this crowd of brazen, impudent, shameless creatures who attitudinize on velvet couches, elevate one leg on a property style, throw a shapely limb over the arm of a chair, or sit on the edge of a table to be photographed in their stage dresses. These Cupids and Pages, who simper and leer from the polished surface of prepared paper, are nonentities rather than actresses. They have gained confidence in the ballet, graduated in slang

and impertinence in that literary monstrosity we call burlesque, and have taken their full degree in the most wonderful of all theatrical institutions—opera buffé.

Speaking charitably, or, it may be, in strict accordance with facts, and looking upon all these semi-nude divinities as patterns of well-meaning modesty, it is lamentable to think what risks they run of being misrepresented. The world is censorious, ill-natured, and malicious; and beauty comparatively unadorned, though ever so well-intentioned, must expect to suffer by companionship with the *demi-monde*, even in a shop-window. The dispensation is hard, but propriety must inevitably lose caste from the most innocent association with *Lais* and *Phryne*. No one "behind the scenes"—that is to say, conversant with things as they really are in the much-abused theatrical profession—would for one moment venture to place these gabblers of half-a-dozen lines, these pretty dolls, elegant dummies, and, happily, speechless Princesses, on an equality with intelligent women able to think, willing to study, and competent to act. There is a wide difference between the two classes, and where actresses, in the strict sense of the word, are known for their ability, these alluring damsels in silken hose, the nattiest of boots, and with no trunks to speak of, are distinguished solely for their reckless assurance, not to say immodesty. Not even the superscription, "Lillie Northbank," in a handwriting as bold as the charming creature herself, recalls any nobler triumph than a breakdown or a vulgar song in a burlesque; and after contemplating the portraits of these small celebrities of the stage, the question, "Who on earth are they?" very naturally follows.

Seriously, this overflow of half-nude figures, ticketed, labelled, and described as representatives of the English stage, is a source of pain, of disgust, and infinite disquiet to the respectable portion, male and female, of the profession. The best of the "players" are, fortunately, not afflicted with this portrait mania. By their absence from the throng they enter a silent protest against an infatuation which cannot minister to the true dignity and honour of their calling. Their reserve, and determination not to follow an unworthy lead, is greatly to their credit; and, seeing the new kind of star now to be found in the theatrical firmament, and multiplied indefinitely in the shop-windows, the choice of the few is not to be wondered at.

An actor may give himself up to pictorial association with others not worthy of the name, or he may decline altogether to have his portrait scattered broadcast over London. There are actors pure and simple, it must be remembered, and there are actor-advertisers. The former are content to be before the public only when following their vocation; but the end and aim of the latter seems to be to keep their names before the public aforesaid at any risk. Which are the worthier, common sense will soon determine. Credulous and unthinking as most people are in matters relating to the stage, there is a certain limit, after all. The least reflective refuse to take it for granted that the actors and actresses they see the most of are the cleverest of the craft; and with this lingering conviction is possibly allied the thought that the less common our men and women of the stage make themselves, the more highly they are likely to be thought of by the world in general. This is the simple truth, and is worthy of consideration by all who have the well-being of their profession at heart.

As for the unpleasant sign of the times to which we have particularly alluded, time and the advent of a purer taste can alone remove it. Nothing can be done to remove this vain thing, which casts a reproach upon the stage. The impure bubble must eventually burst, like any other which rises to the surface of social life; and, in the meantime, the world at large will do well to believe that the respectable section of the dramatic profession is even more scandalized than other people can be at the exhibitions made and the bad taste shown by those bound to uphold the dignity of an honourable calling.

* *Morning Advertiser.*

Correspondence.

VICTORIA CARDS.

DEAR SIR,—We notice in a recent number of your journal, in a letter headed "Albums for New Styles," some remarks relative to Victoria mounts. The firm who sign the letter advance some very unintelligible notions with regard to the demand for novelties, &c. Pray, what are manufacturers and dealers in business for, if not to create a demand for their goods; besides, Messrs. M. are not consistent; they begin by deprecating the introduction of novelties (of which, by-the-by, photographers cannot complain they are surfeited); they give their opinion and dispose of the Victoria mounts as unsuitable, and immediately intrude a novelty in the shape of cameo vignette portraits, any orders for which, we should imagine, would, as much as the Victorias, be so much from the carte or cabinet.

That there is a demand for Victorias the letters of your correspondents and our own experience sufficiently prove. We believe we have done as much, if not more, than any other house in the trade in bringing them to the notice of photographers, and we are receiving orders daily for the same. It is our humble opinion that it is a convenient size between the carte and cabinet, and we feel sure they will come largely into use.

With regard to albums, as Messrs. M. are making them, they can be no further difficulty on that score.—Yours obediently,
97, Newgate Street, E.C. FLEWER AND EVANS.

[Messrs. Flewer and Evans send us some capital examples of mounts of various qualities for the "Victoria cards."—Ed.]

ALBUMS FOR VICTORIA CARDS.

SIR,—When Messrs. Marion and Co. replied to "Middlesex" that he was mistaken in supposing the Victoria albums not obtainable, I and others, including yourself, it would appear, assumed their statement to be simply correct. I shall feel obliged if you will allow me to say that, on applying to Messrs. Marion and Co. on Wednesday last, they replied they had none. They were making some, but that none would be ready for two months.—I remain, sir, respectfully yours,
May 3rd. MIDDLESEX.

THE GRAPHOGENIC V. THE GRAPHOROTATIC.

DEAR SIR,—I cannot quite see of what practical use "Ingenio's" letter is likely to be to any of your readers. In his first paragraph he appears to make out a claim for sympathy in consequence of his endeavours to "astonish" the "photographic world" by the exhibition of his "new tent" having been cut short by the introduction of Mr. Edwards's "photogenic" apparatus. He tells us that his "labour" has been rendered "vain" by the fertile ingenuity of "friend Edwards," and then arrests our sympathizing sigh by the anomalous assurance that his tent possesses virtues which the photogenic apparatus "lacks;" and then he afterwards enumerates at length his grounds for preferring his own "portable bantling" to its disappointing rival.

If "Ingenio's" invention is really better than Mr. Edwards's, I cannot see why he should so impetuously rush at the conclusion that his "labour is vain." Surely photographers have sufficiently quick discernment both to distinguish and appreciate. Let "Ingenio," who objects so strongly to patenting ideas, show us his roomy tent "running on wheels," and presenting so many conveniences, and carrying so much, and I, for one, will thank him.

I am an old photographer, and have experimented long and largely with tents of various construction, all good in their way; but I have had no hesitation in applying Mr. Edwards's invention to one of my cameras, which I hope to take with me to the top of the Caradoc in about a week.

A tent upon wheels, however cleverly constructed (and ingeniously the one now especially referred to no doubt is, as its patronymic clearly implies), I question whether many of your readers would not find insuperable difficulties in dragging or pulling up ascents which I hope to mount with ease, even with the few pounds additional weight of the graphogenic apparatus.

I have had some correspondence with Mr. Edwards on the subject of his application of india-rubber to his portable bath,

and have ventured to suggest that the easy replacement of this substance should be considered in the construction of the apparatus, which, I am happy to find, has been done.

I am a dry-plate worker of twenty years' standing, but I can assure your readers that I hail the introduction of the "graphogenic" with great confidence; that I shall find in it all the necessary conditions for working the wet process out of doors with ease and certainty.

My impressions entirely accord with your own, that Mr. Edwards's invention is of great value, and leaves little to be desired. Still, I hope, for his own sake, no less than for that of the photographic fraternity, "Ingenio" will bring his invention out of the "cold shade" into which his diffidence has needlessly thrust it, for elucidation in your valuable pages.

By way of distinction, perhaps it might be as well to call "Ingenio's" invention the "Graphorotatic," or, which may possibly be preferable, the "Photorotatic."—I remain, dear sir, yours faithfully,
W. L.

THE GRAPHOGENIC APPARATUS.

DEAR SIR,—I read with regret the remarks of "Ingenio" in last week's NEWS, respecting Mr. B. J. Edwards's "Graphogenic," and, as both Mr. Edwards and "Ingenio" are entire strangers to me, you will see that personal objects are not the reason of my writing. In the interest of the profession, anything new should not be attacked in the way "Ingenio" attacks the Graphogenic, as of course, if he himself does not approve of it, the remedy is simple—he can leave it alone. But why abuse it to the loss of the patentee? Such criticism, in my mind, is calculated to deter others (not such veterans as Mr. Edwards) from making known their inventions, to the loss of the profession. I think if such gentleman as "Ingenio" cannot do anything for the advancement of photography, they should not waste their brains (if they have any) in conceiving ideas to retard its progress. If I remember rightly, "Ingenio" attacked Mr. Edwards's combination printing frames in something the same way, evidently showing there is a little personal feeling in the matter; at any rate, it looks like it. I myself think that we ought to be grateful to Mr. Edwards for his endless contributions to the NEWS. Only a fortnight ago we read of his developer, which, I might say, I tried with marvellous results.

Hoping I have not occupied too much of your valuable space, I am, sir, yours respectfully,
Justice.

May 2nd, 1871.

PS.—"Ingenio's" hope of astonishing the world is not gone if he has anything better to bring out.

DEAR SIR,—Many thanks to your correspondent "Ingenio" for calling attention to the advantages of the graphogenic apparatus for out-door photography compared with his "roomy" running on wheels contrivance, capable of carrying camera, chemicals, great coat, umbrella, and "grub." Photographers are well acquainted (to their cost) with the "virtues" of similar cumbersome appliances; it now remains for them to test the efficiency of the simple means I have introduced of getting rid of the "impedimenta" and discomfort hitherto connected with manipulating wet plates in the field. I am content to wait their verdict. Meantime, if your correspondent has room for other "ideas" than his own, let him give us his opinion, after actual trial, of the developer of which I have given the formula. This "idea" I have not patented; but, if I may judge from the number of letters of approval which I have received, it is considered a matter of no small importance, and is already "esteemed" so highly that it is exclusively used in many of the best photographic establishments.

I cannot understand why "Ingenio" should be so anxious to break a lance with me, unless it be that, remembering his former defeat, he wishes to redoem his laurels. If so, I have no objection, but would suggest that he select a more appropriate "nom de plume," or adopt the more manly course of signing his own name, which, after all, may not be utterly unknown to yours very truly,
B. J. EDWARDS.

SIR,—Will you allow me to ask a few questions of your correspondent "Ingenio?"

I. Has he seen the open air apparatus of Mr. Edwards?

II. If he has seen it, has he anything better to suggest?

III. Why he does not describe something better, instead of sneering at something good?

Readers of the NEWS will scarcely thank him for speaking with contempt of an invention of which the Editor has spoken so highly, unless he is prepared to show them a "more excellent way."—Very respectfully yours, SCRUTATOR.

PS.—Is it possible, as a friend has just suggested, that "Ingenio" is a friend of Mr. Edwards, adopting the old theatrical dodge of aiding in puffing a thing by pitching into it, so as to admit of further publicity in letters of defence?

RETOUCHING OLD NEGATIVES.

DEAR SIR,—I had occasion a day or two since to retouch an old negative, but found that, owing to the glass-like surface of the varnish, the pencil would not "bite." I then thought that if I could possibly give a so-called "tooth" to the varnished surface, it would answer the purpose, and I may say the plan I adopted was perfectly successful.

I dust a little fine flour emery over the surface of varnish, and, with a light circular motion of the finger, rub the powder until a mat-like surface is produced on the negative. You will find the pencil take nicely. Try it, Mr. Editor, and if you think it worth noting in the NEWS, do so; if not, drop this note in your waste paper basket.—Yours, &c.

May 2nd, 1871.

W. BRITTON, JUNR.

Talk in the Studio.

¹ PHOTOGRAPHIC SOCIETY OF LONDON.—The next meeting will be held on Tuesday, 9th May, at the Conduit Street Gallery, when Lord Lindsay has kindly promised to exhibit his eclipse apparatus, and Mr. Ernest Edwards, B.A., to describe the mode of working his heliotype printing process. Novelties in the way of apparatus will also be shown by Col. Stuart Wortley and Mr. Whiting; and the prize prints of the Amateur Photographic Association will be exhibited.

WHERE TO GO WITH THE CAMERA.—A "Practical Man" remarks:—"In addition to hints as to where to go, it may be satisfactory to many who intend taking a summer trip for a week or two, to point out what they are likely to meet with in the shape of 'camera food.' Every county and district have peculiar and different features; and, by hinting at and pointing out the same, a choice will be offered to excursionists as to different objects of interest and places of note, so that they may have an opportunity of selecting a route that may yield a series of subjects coming up to their wishes and wants. The individual wishing for a collection of 'bits' of the lake order would be somewhat ashore at the Land's End; and the one desiring quiet, sylvan, sleepy, cozy hollows would be terribly abroad among the rough tors, granite boulders, cromlechs, and huge monoliths of Dartmoor and the Carradon Downs. The district pointed out by a gentleman in the NEWS of the 21st is an admirable one, and will well repay a visit. Any one inclined to try the same place might possibly find some advantage in proceeding from London direct to Birmingham, the once 'Hardware Village,' now the great iron metropolis of the Midlands. Here he will find much of interest and beauty at Aston Hall, the once noble and interesting mansion of the Holte family, built in 1618. Here he will find a great hall and decorated ceiling, a great staircase and grotesque carving, a great drawing room, and a gallery 136 feet long, with ornamented ceiling and magnificent chimney-piece. Then Astou Park, the property of the Corporation, with the fine avenue of trees, planted during the reign of James I. A judicious hunt up and look out will yield a vast amount of most interesting pictures, proving that the great city of brass and huttons can yield many good things in addition to pins, needles, steel pens, frying-pans, and iron candlesticks. From the Great Western Station, Snow Hill, Warwick can be reached in twenty-one miles, Leamington in twenty-three, and Stratford-on-Avon twenty-seven; or, from the Great Central Station in New Street, where the Western and Midland lines converge, Rugby can be reached in thirty miles, Kenilworth in twenty-five. By this same line visits may be paid to Lichfield, with its Cathedral; Tamworth, Burton-on-Trent, Derby, and Nottingham, on the north and east; and Cheltenham and Gloucester on the south-west. It would take a large amount of room and space to note down or hint at a

tithe of the 'bits,' views, churches, mansions, old bridges, old mills, and the thousand and one objects of interest and places of note to be met with round and about the various places named and indicated. Much of this can be supplied by a reference to any of the guide-hooks or maps now so plentiful, and of such use and value to the tourist."

MATCHES AND PHOTOGRAPHS.—The Chancellor of the Exchequer, it seems, never doubting, that his match tax would receive the approval of the House, had already prepared a large stock of stamps for the boxes. Mr. Bernal Osborne discovers that the motto intended for matches will answer equally well for photographs, and recommends a tax on portraits simply to utilize the stamps. In a recent speech in the House he said:—"The right hon. gentleman (Mr. Lowe) has gone to considerable expense—not himself, because we shall have to pay it—in having a new stamp, with the motto, *Ex luce lucellum*, which, for the benefit of the successful capitalists I see around me—I may say means, 'From light a little gain' (laughter). Well, the stamp is ready, why should he not attach that motto—and it is apposite to the subject—in the way suggested by an hon. gentleman who sat behind me the other night, and who, after attacking his budget most furiously, made it up with him and walked into the same lobby—I mean the hon. member for the City of London. I say, why should he not attach that *ex luce lucellum* to the trade in photographs? (a laugh.) Such a tax would be quite unobjectionable, being a tax on the vanity of men and women (loud laughter), and not a necessity of life, and we may be assured, for the reason I have stated, that it will be a most successful tax (hear, hear). Well, as *ex luce lucellum* is ready, let him apply it in that way, and take something off our income tax (cheers and laughter)." During a subsequent debate Mr. O. Morgan remarked:—"The hon. member for Waterford suggested a tax on photographs, with the view of utilizing the device "*Ex luce lucellum*." Having been himself a victim of that diabolical art, he should have no objection to a prohibitory tax on photographs; but he strongly suspected that if that suggestion were adopted, some hon. gentleman opposite would discover that photographic chemicals were produced at the East End, and there would be a procession of photographers with a petition, just as there had been a procession of lucifer match makers ('hear,' and a laugh)." Mr. Morgan is ungrateful for unusual privileges. We have reason to believe that the first photograph for which he sat was produced by Dr. Diamond, whose rare skill in securing portraits which ennobled the "victim" is well known to all familiar with his work. When Mr. Morgan's photograph was shown to various friends, it caused a serious tax on Dr. Diamond's friendly courtesy, so many wished to secure photographs equally pleasing. Amongst others at the time were Mr. Edward Hawkins, F.R.S., chief of the Antiquity Department of the British Museum, and the well-known author of the "Lives of the Judges." As Mr. Morgan was not "taxed" in any way for his photograph, it is ungrateful to wish to see photograph taxed.

PHOTOGRAPHIC ADVERTISING.—Anthony's *Bulletin*, explaining a plan of photographic advertising devised by Mr. H. M. Boozer, says:—"Photographic advertising is based on the fact that no advertisement is equal to that of the personal presence of the proprietor himself—this being the next thing to it. Any system that can, at not too great cost, make him more generally known to the public, in connection with the business he represents, does for him and his business a great work. It makes doubly effective all he has done, is doing, or may do, with printer's ink. Being thus known, he is liable to be making sale or purchase, as the case may be, equally as well abroad as at home—thus greatly enlarging his sphere of operations by placing him outside the limits to which circumstances have otherwise assigned him. It is of great value to be thus known, and of great advantage to the public generally in their relations to each other. Pope's truism, 'The proper study of mankind is man,' is a very pertinent one in this connection. In the study of the pictorial, it is rare to find greater general attraction than the gallery of portraits, especially when with their originals there is more or less partial acquaintance; and experience has demonstrated that the photographed human face will hold the attention of both the student and the curiosity seeker sufficiently to secure the attentive reading of the ideas printed in connection. A very wealthy and practical business man, who had just made a gift of \$25,000 to an educational establishment, remarked: 'I have always had a great

personal antipathy to having my likeness in the hands of others; but I see this is based upon sound business principles, and as such I recognize its real value, and give it my cordial support. It is one of the best things that has ever come up for business men, and I hope to soon see it in universal use."

GERMAN PHOTOGRAPHIC SOCIETY IN AMERICA.—In New York is a photographic society consisting entirely of German photographers, of which Mr. Kurtz has just been appointed president for the ensuing year. The third anniversary just held appears to have been a gay social reunion. From our esteemed Philadelphia contemporary we learn that "the members had come from far and near; from the city, the suburbs, and the country. They all came to a focus around their fair partners. A merrier and more family-like party it would have been hard to find. The rooms were decorated fittingly for the occasion. A splendid camera-box and tube stood in the centre window, draped by American and German flags, surmounted by a large solar print of Dr. Vogel. The walls were hung with specimens of all styles of photographs, portraits of every variety of light effect, out door views, Albertypes, photo-lithographs, &c., the whole tastefully surrounded by evergreens and national emblems. After tripping the light fantastic toe after the enchanting melodies of Strauss, Offenbach, &c., the company sat down to a solid repast. The first toast drank was "The Photographic Art and the German Photographers' Society." It was responded to by Vice President O. Lewin in a few happily chosen and appropriate remarks. The next was 'Dr. Vogel, the eminent labourer in our art and the genial companion,' given by Mr. Ch. Hansgrath. The last one was 'The Ladies,' responded to by Mr. H. Schoene in some very nice rhymes. Geniality and good humour reigned supreme, and we did not adjourn till the first rays of morning admonished us to go home to the sweet home of the skylight."

SUBSTITUTE FOR ALBUMEN.—The *Scientific American* says: "The enormous consumption of whites of eggs in albumenizing paper for photographic purposes may be doomed to come to an end. *Dingler's Journal* announces a substitute for albumen for this purpose, under the name of lactarine. It is a white or slightly yellow powder, with the odour of casein. When subjected to ether, a small amount of saponaceous fat may be extracted from the mixture. The powder resists water, but is accessible to the influence of the alkalies, either caustic or carbonated. Treated with the proper proportion of either acetic or hydrochloric acid, a curd is precipitated, which is found to be soluble in excess of the acid. In use, it is dissolved in ammonia, and can be coloured to any required shade.

To Correspondents.

BEGINNER.—There are several causes which may occasion the excited paper to dry irregularly, producing the spots of which you complain, and which you will find caused by the solution accumulating in drops instead of draining off regularly. One cause is, with some samples of paper, the use of a silver bath stronger than is necessary. Another cause is, keeping the paper in an exceedingly dry place before exciting it, so that it is very repellent to the solution. The remedy consists in using the silver bath of the strength recommended by the manufacturer for the paper in question; or keeping the paper in a slightly damp atmosphere a short time before exciting the paper. Whenever the silver solution is seen to stand in drops on the paper instead of floating off in an even wave, or when the drops are seen to have formed soon after the paper is hung up to drain and dry, the use of a piece of clean blotting-paper will remove the evil. 2. When your toning bath becomes pink, it shows that the gold is in process of precipitation, and the bath will soon be useless. It may be the result of various causes. Sometimes merely standing in the light will produce this result; sometimes contamination with dirty fingers; and sometimes an alkali condition will produce this result. 3. Add a drop of pure nitric acid to your bath. If the streaks do not disappear, neutralize and sun it. Sometimes moving the plate in the bath laterally during the process of sensitizing will remove the tendency to vertical streaks.

L. G.—If a photograph be not registered before copies are sold and circulated, the copyright is lost. No copyright is secured in portraits taken in the ordinary way of trade without an express agreement in writing between the parties

X. O.—If the facts are as you state them, you are quite safe. You are in no sense breaking the law.

DRY-PLATE.—We have not tried the process in question, but we suspect that the cause of failure is thorough washing after first sensitizing. The washing should be only very slight, we think, to secure any good degree of sensitiveness. Further, you should develop with pyrogallic solution to which a few drops of silver solution have been added. Give a full exposure—at least six times as long as for a wet plate.

V. D. MAYER.—The lenses commonly used in magic lanterns are of a much less perfect character, and different construction, to those used in photography. They are usually of larger size, shorter focus, and non-achromatic. A photographic lens may be used for a magic lantern, and will give much finer definition than the common lens; but, as a rule, a much smaller field of illumination must content the experimentalist.

J. W. S.—We cannot speak with certainty of the amount of structure in various commercial samples of collodion, but as the presence of high temperature and full proportion in the preparation of the pyroxyline tend to the production of structureless collodion, that sold as Hurdwisch's collodion, said to be made on such principles, is most likely to suit your purpose. Pyrogallic acid development will undoubtedly yield a more amorphous deposit than iron development; and, since rapidity is not an object, we recommend the pyro for your purpose. 2. We cannot speak with certainty of the structural condition of any of the commercial dry plates. 3. With a suitable collodion, we apprehend that any of the dry processes would answer, and that alkaline development would be favourable to your purposes.

G. LEWIS.—The gum-gallic plate without backing reached us in fragments: that with the backing whole. We exposed the latter, and found no especial defect in it; but from your description, and from the appearance of the wet process negatives enclosed, we are disposed to regard slight over-iodizing of the collodion as the cause of the irregular streaks. Try diluting each ounce with about a quarter of an ounce of plain collodion. The thin fogged effect of the negatives suggests that your collodion is new and unripe, or that your bath is out of condition. Try the addition of a drop of utric acid, to remove the tendency to fog. If that does not succeed, try neutralizing and sunning. Your collodion seems to be thin and wanting in body. Is this so? If so, try adding a little pyroxyline. Your chemicals must all be in good condition, and working well in the wet process before you commence to prepare dry plates.

S. H. JEFFRYES is glad to find other photographers are taking up the idea of "scroll" or "effectograph" portraits, but wishes it to be remembered that he first worked out the idea, and suggested it to our readers. He encloses us some examples with fresh designs, in which a ribbon or scroll surrounds an oval with inscriptions, such as "Yours sincerely," in the scroll. He says:—"I beg to hand the same to illustrate what photographic printing can be made to do, being two of my latest designs in "effectography," all being finished in the printing frame, and requiring no extra touching with pencil or colour. Various devices, of course, be used in the shape of words, &c., according to the desire of customer, or the oval shape can be printed in blank to allow of an ordinary medallion bust to be mounted in the usual way, and allow of the callographic device being kept in stock ready for use, and making an advantageous use of the carte-de-visite full length negative as well as the vignette.—I remain, yours respectfully, S. H. Jeffryes."

TIBER.—After a picture is burnt in it can only be removed by grinding away the surface of the tablet.

J. CUNNINGTON.—In our next.

MODES OF OBTAINING LARGE PHOTOGRAPHS.

FOR some years past there has been a growing taste for large photographs. This taste, which seems to arise as a reaction upon the rage for card and cabinet pictures, is not necessarily in any degree antagonistic to the popularity of the smaller sizes, but may be cultivated as opening a new branch of the art, rather than superseding anything in existence. The desire for photographs which may be framed and hung has always existed in greater or less degree, but, from a variety of causes, has never been fully met. That the desire and taste are increasing is manifest from varied forms of evidence. Nothing has better illustrated the direction of photographic taste than the character of the pictures contributed to photographic exhibitions during the last two or three years. There has been at each exhibition a general resemblance in the degrees of excellence and in the qualities upon which excellence has depended; but there has been a steady growth of size. Three or four years ago the rage for what has been termed Salomoneseque portraiture set in. At first the size of the French master was adopted, and ten by eight portraits became common; next we had an advance to twelve by ten; then came Mr. Blanchard's grand examples of the same style, extended in size to sixteen by twelve, and Mr. Slingsby's noble portraits on whole sheets of paper. Mr. Warwick Brookes, and others, illustrated the same tendency in portraiture, and Col. Stuart Wortley in his fine and massive portrait studies. Instantaneous sea views, with the exception of one or two *tours de force* by Le Gray, used to be confined to stereoscopic slides; but we have of late the magnificent pictures of this class, sixteen by twelve in size, by Messrs. Robinson and Cherrill, and the still larger examples by Col. Stuart Wortley. In landscape we have had the noble pictures of Mr. Earl, and others, all tending in the same direction.

It may, of course, be remarked that the production of photographs of large size is no novelty: it is not; but the production of photographs of large size and exquisite excellence is a novelty. We have no hesitation in saying that the introduction of the card machine to a revolution in photographic manipulation. A degree of excellence before unknown, or, at least, very exceptionally obtained, became imperative. First came mechanical perfection, in the shape of clean, spotless, stainless, negatives; freedom from mess and irregularity in backgrounds;

then delicacy of gradation, modelling, and diffusion of definition; and gradually, in greater or less degree, higher artistic qualities, or, at least, more general diffusion of the appreciation of and desire for artistic qualities. The influence of the education and progress in photography thus achieved by small work has of late years shown itself in more ambitious pictures, and large photographs are now produced which are well worthy of taking the place of engravings for domestic mural decoration.

When Mr. Dunmore, in a recent paper, called the attention of the South London Society to the demand for large photographs, his statement was endorsed by those who may be trusted as exponents of public taste in the matter. These, and other evidences not necessary to examine in detail, demonstrate the fact that, both amongst photographers and the public, large photographs are growing in favour.

The question, important to many, will arise, as to which is the best method of producing large pictures. Many, possessed of the necessary appliances in the shape of lenses and cameras, will declare at once that, within certain reasonable limits, the production direct of the negatives of the full size is the best method; and they might point triumphantly to the examples exhibited at the last exhibition in confirmation of their views. Unfortunately, however, to many photographers, especially amateurs and portraitists with modest establishments, the facilities for such direct work are inaccessible, whilst the work itself would be difficult. For these, and many other reasons, the production of small negatives, with a view to the subsequent production of large prints, presents itself as the most desirable and available mode of working. The best mode of enlarging becomes, then, the important consideration. The use of the solar camera possesses undoubtedly many advantages. The finest possible enlarged prints are obtained by printing-out on albumenized paper by means of the solar camera. But the days upon which this process is possible in England are so few and so uncertain that no steady reliance can be placed upon this as an available method. Developed prints, with very rare exceptions, are not sufficiently perfect to be of value without considerable retouching; and if developed prints were perfect, or sunny days plentiful and certain, the solar camera demands an extent of space for its arrangement, and experience for its working, quite beyond the reach of a very large number of photographers. Development printing by the aid of the magnesium light, and the production of enlarged negatives to print direct, both possess advantages, but, as a rule, the productions require considerable retouching. Mr. Dunmore, in his recent paper before the Photographic Society, called especial attention to the advantages of the production of enlarged paper negatives as an aid to the production of large prints, and as we some years ago

recommended a similar course, we are quite prepared to endorse Mr. Dunmore's recommendation now.

For large pictures, as we have before pointed out, paper negatives possess many recommendations. The minor advantages of decreased risk and trouble in printing and storage need not be dwelt upon: but the especial facilities they present for the intervention of the skill of the artist is of vital importance. It rarely happens that a photographic portrait approaching in any degree to life-size possesses, or can possess, sufficient delicacy to be tolerable without retouching. Minor defects inherent in the art, minor defects belonging to the model, scarcely appreciable in a small picture, become very offensive when rendered on a large scale. So landscape photographs, which, when small, are suggestive little gems, become, when large, no longer suggestive, but bald and empty, requiring the ameliorating touch of the artist in various directions. The art of retouching negatives skilfully on glass has of late, it is true, attained a high degree of perfection, but for large pictures the broad treatment desirable would be scarcely possible on the glass negative. The retouching of a paper negative, either with lead pencil, chalk, or water colour, is a comparatively easy thing, and, in artistic hands, capable of broad, free treatment, comparatively little work will yield admirable results. With a negative so treated, the prints need present no obtrusive evidence of manipulation, and each print is perfect without further touching.

Large paper negatives may be produced in various ways. Regarding some very fine ones exhibited by Mr. Dunmore at the Society, he was not, unfortunately, able to give details of production beyond the fact that the solar camera had been employed; and he suggested that if photographers generally gave attention to the importance of such pictures, it was probable that the production of the negatives from small negatives supplied might become a branch of trade. This would, of course, meet many purposes, but not all. Many photographers prefer, if possible, to do all their own work; some object to send their negatives out of their own possession: and, for various other reasons, it is often desirable to have a simple means at hand of effecting the work at home if desired.

The simplest method of producing paper negatives with which we are acquainted, is one we have often practised with success. It consists, first, in producing from the negative a good, vigorous, well-exposed transparency of the size desired. This is easily effected without extensive or expensive appliances: a small room—the ordinary dark room will often answer—which can be made dark: a hole in the shutter to admit of the negative: a good card lens; and a screen upon which to rest the sensitive plate: the appliances, in short, which we have before described for producing the transparencies for Seeley's photo-crayons. Thus equipped, without large camera or lens, the large transparency can easily be produced. From this it is simply necessary to produce the negative on paper by contact printing. We have found that a piece of albumenized paper, immersed in the bath instead of floating, printed deeply, and fixed without toning, would generally give a negative of sufficient printing vigour admirably suited for working upon, the highest lights being applied by the pencil. Where sufficient vigour is not obtained by printing-out, development printing may be adopted, the ordinary calotype formula being used, and a few seconds only of exposure in the printing frame. We have found also that paper prepared with flour of silver, printed until a slight image appeared, and then developed with gall-nut, gave an image of fine tonal colour, well suited for printing purposes. The paper negative, after finishing and toning, should, of course, be waxed, to render the paper transparent, in the manner generally employed in the calotype process.

ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

EX LUCE LUCELLUM—PHOTOGRAPHY AT THE INTERNATIONAL EXHIBITION—VICTORIA CARDS—THE GRAPHOGENIC APPARATUS—THE PHOTOGRAPHIC SOCIETY OF SCOTLAND.

PHOTOGRAPHS and photographers, it seems, have this time had a narrow escape from taxation. Members of Parliament, various journals, and common gossip, have been marvellously unanimous in concluding that photographs ought to be taxed, although very diverse reasons have been alleged as justifying such taxation. Mr. Crawford, in the House of Commons, suggested that photographs should be taxed instead of matches, because they were taxed in America as well as matches. Mr. Crawford evidently did not know that the tax had been found in America to be so irksome and inconvenient that at the earliest opportunity it was removed. Mr. Crawford could scarcely be seriously blamed for ignorance of the removal of the tax, when a photographic journal did not know, and referred to the tax as still in existence. Mr. Bernal Osborne recommended that photographs should be taxed, because the stamps prepared for the match boxes might be used for photographs, the motto thereon, *Ex luce lucellum* (from light a little gain), would apply equally as well for photographs as for matches. Mr. Osborne's joke loses point, from the fact that the stamps intended to bind round match boxes, preventing the opening without destroying the stamp, would scarcely have been available upon *cortes-de-riviste*. Mr. O. Morgan would tax photography, because it was a "diabolical art" of which he had been a victim; possibly looking glasses might be taxed and railed against on similar grounds. It is fortunate, however, that the Chancellor of the Exchequer is not fond of suggestions, otherwise the weakness of the reasons for imposing the tax would not have saved the photographs. They are safe now, however, for twelve months.

The display of photographs at the International Exhibition is now accessible to the public, and, whilst the excellence of the examples cannot be impeached, nor what you have termed the representative character of the contributions, I think few people can fail to be disappointed at the limited, I had almost written insignificant, proportions of the display. The official report for photography at the Exhibition of 1862, having done justice to the really magnificent collection of photographs then shown, and recognized the progress made since the former Exhibition in 1851, expressed a belief that the next International Exhibition would show results to which those he had just described would "bear but a small proportion in beauty, vastness, and importance." That in some element of beauty there is advance there can be no doubt, but in other respects this is almost a travesty of the 1862 display. The limited space devoted to photographs, in the first place, and the plentiful lack of novelty which prevails in the next place, tend sadly to rob the Exhibition of interest. Another year, it is to be hoped, photography will occupy a more creditable position. Nothing is so detrimental to the completeness of a display of this kind as uncertainty, and this element has prevailed throughout the arrangements for photography at this Exhibition. There was uncertainty as to when application was to be made, uncertainty as to what space could be devoted to the department, uncertainty as to the space available for any individual, uncertainty as to the material to which the photographs were to be submitted for selection, and uncertainty, as it finally turned out, as to whether novelties were at all a desirable condition in regard to the pictures sent to compete for places. Seeley and his fellow-workers, indeed, to be prevailing defects of the photographic department which prevailed at South Kensington, and, indeed, on the opening day of the Exhibition, in a pair of crumpled medals. Mr. Nottage and Mr. England, armed with every kind of "pass"

and "permit" which forethought could devise and secure, and prepared with suitable appliances for obtaining negatives of the opening ceremony, found themselves at the vital moment thwarted at every point by petty officialism armed with a little brief authority, and so the golden opportunity passed, for which a heavy premium had been paid, without a plate exposed. The same indefinite and uncertain element prevailed in relation to many of the tickets sent out, which kept groups of ladies in the streets around the doors with tickets, apparently intended to admit them to the ceremony, in their hands. It appears to have been a joke indulged in by the official mind to prepare tickets, apparently to admit to the "opening ceremony," which the official mind in charge of the turnstiles could construe as only admitting after the ceremony.

Returning to the photographs, however, after allowing for the serious detriment effected by this element of uncertainty, it must be admitted that the committee have done their best with the space at their disposal, and the photographs sent to fill it. The pictures are arranged and hung admirably, as, with the great experience in such matters of Dr. Diamond, they could scarcely fail to be; and the general effect, so far as it goes, is excellent. The jealous alarms which seemed to have been aroused by a possible competitor taking part in selecting and arranging, and which appears to have been groundless, soon subsided when it was known that none of the committee would exhibit. I have heard the question asked, it is true, how far this pact is maintained when Col. Stuart Wortley exhibits in the conservatory. The fact that a few fine transparencies from his negatives are effectively used as adding to the decorative arrangements cannot in any sense be construed into exhibiting; and, being apart from the photographic department, they cannot be supposed for a moment to affect, or be affected by, the selection of photographs in the photographic department.

I cannot learn that the Victoria card anywhere meets with warm favour in this country. I hear many photographers say, "Oh, I shall go in for them when the demand has set in," which is, of course, a very easy and tranquil sort of enterprize, and somewhat reminds one of the dictum of fond parents, who forbid their sons to bathe until they have learnt to swim. The demand cannot come until photographers have created it. Whether the thing is worth the effort of creating a demand for it I do not now discuss, beyond remarking that, as a rule, anything is worth the slight effort required here, which will give a new stimulus to the business of the portraitist.

The new apparatus patented by Mr. B. J. Edwards for obtaining negatives without a dark room is likely to prove a boon to many. I do not like the name "graphogeuic;" it may be "natural" and Greek, but it is not descriptive. Without some account of its purpose, no one would arrive at a conclusion of its real character merely from its name. But the invention itself seems to be most valuable, and if in practice it is found to carry out all its promise, I shall not be surprised to see it create a revolution in amateur, and possibly in professional, photography.

The Photographic Society of Scotland, it seems, is in a singular dilemma: it possesses funds for which it is unable to find a legitimate purpose, and, in sheer despair, proposes to establish some memento of its existence—not by means of photography in any form, not even by establishing a photographic scholarship, or a photographic charity, but by purchasing a painting (!) to be presented to the Royal Scottish Academy. Who shall say in future that photography has not been a handmaiden to art? I remember hearing a gentleman say, when he received back the unused balance of his contribution to the "Goddard Fund," that he was uncertain whether to hand it over to the Earlswood Asylum for Idiots, or the Hanwell Lunatic Asylum. But amid the projects for disposal of

the Scottish Society's money, is it not strange that no one has thought of presenting part of the sum to the London Photographic Society? In its state of renewed vitality and activity, there can be little doubt that it could use the money to great advantage for the art; and the act would be one of rare and fraternal gracefulness.

A HIGHLY SENSITIVE PAPER FOR PRINTING BY DEVELOPMENT.

A METHOD of preparing a very sensitive paper for the solar camera is given in *Licht*, which allows of the possibility of obtaining pictures by this apparatus in dull and unfavourable weather. Ordinary paper which has been prepared with arrowroot, and treated with a salting solution, is floated, for the space of three minutes, upon a mercurial solution, prepared according to the undermentioned formula:—

Water 2½ litres, or 88 ozs.
Bichloride of mercury... 125 grammes

After treatment for the above period, the sheets of paper are removed from the solution and hung up to dry. When perfectly desiccated the sheets are further floated on a bath of—

Water 30 cub. cents., or 1½ ozs.
Nitrate of silver... 1½ grammes

A couple of minutes suffice for this operation, and the paper is then in a state of exquisite sensitiveness. On this account great care must be taken that, after the second treatment, the sheets are well preserved and sheltered from the action of light, which acts upon the surface with surprising rapidity.

After exposure to the action of the solar rays, stretched upon the screen in the ordinary manner, the image is forthwith developed by immersion in an iron developer compounded in the following proportions:—

Water 2½ litres
Sulphate of iron 95 grammes
Acetic acid 190 cub. cents.

In this solution the sheet of paper is allowed to remain until the picture is perfectly developed, when it is rinsed, fixed in a hyposulphite of soda bath (1 part soda to 4 parts water), and finally subjected to a thorough washing.

AMERICAN CORRESPONDENCE.

PHOTOGRAPHY IN MONTREAL—RETOUCHING STUMP—A CURIOUS CASE—OUR EXHIBITION.

A WARM desire to see a Canada winter induced me to go from Littleton to Montreal. I had seen Montreal before, in the autumn, when the capering breezes had barely awakened, when the trees were yet fresh and green, and when the noble St. Lawrence hurried by, tumbling over the rapids near by, as if hastening on with some message of love; but, as our mutual good friend, Mr. Notman, declared, I had never seen Montreal in winter. I have now, and I am happy in the experience. A brighter, merrier city than Montreal in mid-winter can scarcely be imagined, at least, so far as the streets are concerned. The first considerable snow is the signal for bidding farewell to anything like conveyances on wheels. The family carriage and the cumbersome carts are alike stowed away, and the sleighs, and the sleds, and the jingling bells are brought out in their place, and are what make the city so full of life. The tough Canadian ponies never go on a walk, so you can imagine the scene when the broad streets are filled with sleighs and sleds, going hither and thither, every horse on a trot, whether hauling a load of hay, or carrying a sleigh-load of merry children. One unaccustomed to such scenes becomes quite excited over it, and charmed with the novelty.

In the evenings Montreal is also gay, for then the skating rinks are the great attraction, and he is a dull boy who

cannot find pleasure there amid the games of la crosse, skating, snow-shoeing, &c. There is no more pleasant scene than a motley crowd gliding over the ice on one of these great rinks, while the music enlivens the brain, and all sorts of catastrophes excite the risibles. Among the other amusements at these rinks, I must tell you of one which I saw enacted at the great Victoria Riuk, a photograph of which you have from Mr. Notman. A number of headless barrels are laid down upon the ice, side by side, in different parts of the rink, their open ends towards the starting point. A lot of half-grown boys on skates are then let loose, and, like hungry hounds, they make for these barrels. The luckiest ones get their heads in the barrels first, and then their object is to struggle through the barrels, skate on to the next ones, and so on through them, and around the rink several time, the one "going through" the most barrels being the victor. You can imagine how ludicrous it looks to see a dozen lads rolling over and over in these barrels in their struggles to rid themselves of their appendages. It is quite as amusing as to see a lot of crabs going it sideways over the beach with their partly shed shells on their backs, only much more so.

But this is not photography. I could tell you many things about Montreal, and the social, hospitable subjects of your beloved Queen who reside there, and of how the noisy St. Lawrence is hushed, her bosom nought but one solid cake of ice, and of how we crossed the river to the French village on the other side, and of how we rode upon the river for miles; but I must not occupy so much space with such details.

Photography in Montreal is undoubtedly headed by Mr. Wm. Notman, with whose admirable work you are well acquainted. He has an immense establishment, with a large force of assistants, and the quantity and quality of work turned out there by no means allows one to feel that photography has had its day, as some croakers aver. Mr. Notman's average plain photography equals any that is made in the world, without doubt, both in excellence of manipulation and in pictorial effect. His profession was that of an artist before he undertook photography, and he is still an artist of the strictest sect, making and educating all of his employées to work to that great end in photography, *i. e.* pictorial excellence. Such men in the profession have a wide influence upon others, and I only wish we had one in every city. Mr. Notman makes all sizes, from the carte-de-visite to life-size, and employs five or six artists to colour. Composition pictures are in considerable demand with him, and he makes them of all sizes, from those with hundreds of figures in, as the Skating Carnival, which you have, down to small groups in the family library. How he does these I will try to tell you in some future letter. If you will visit our coming Exhibition in Philadelphia, you shall see a fine display of Mr. Notman's work, without the trouble of going to Montreal, although he has authorised me to invite you to visit him if you do come to the Exhibition. I assure you of a sound welcome at both places.

Mr. Alex. Henderson is also a very skilful photographer in Montreal. Besides a good portrait business, he also gives much attention to out-door work, and showed me some excellent things, both from wet and dry plates. Mr. Henderson is an ambitious artist, constantly striving to excel, and I am glad to say he is successful.

Mr. J. Inglis is also a growing photographer, producing excellent work, and always striving to do better. You are familiar with his work also, as I have seen it noticed in your columns. Mr. Inglis deserves great credit for his persistence and energy in trying to make himself one of the best.

There are many other photographers in Montreal, but the above are the principal ones. Mr. Notman also has a branch at Toronto, in connection with one of his best artists, Mr. Jno. A. Fraser (firm Notman and Fraser), to which I paid a visit on my return home; and also branches at

Ottawa, Halifax, N.S., and St. John, N.B. Thus you see the good elements are spreading hither and thither.

There is also another place of photographic interest here. I allude to the photo-lithographic establishment of Messrs. Geo. Desbarats and Co. You some time ago described the Leggotype process in your pages, a process for obtaining transfers upon stone, which may be printed in the steam lithographic press, and the invention of Mr. W. A. Leggo, of Montreal. While many others have been experimenting to obtain a method of reproducing drawings and photographs from nature, these gentlemen have quietly accomplished it, as you shall see by the specimens I send you. I mail you several copies of the *Canadian Illustrated News*. It is published by Mr. Desbarats, and the whole outside pages, letter press, portraits, landscapes, and all, are printed in the steam lithographic press. You observe that the illustrations are of no mean quality. The services of an etcher are made considerable use of, as you see, on the negatives, before the exposure of the film is made, and it would defy any one to tell some of the results from the finest wood cuts, while they are produced at a comparatively small price.

Mr. Desbarats has everything here in the neatest and best of shape. His glass house, 28 by 34 feet, is arranged principally for purposes of reproduction, and he uses the Ross wide-angle doublet lenses, having one of eight inches diameter mounted on a huge camera, and another smaller one, in use. It is a model establishment, and a credit to any country. For many years Mr. Desbarats was printer to the Queen in Ottawa, and his father before him. I wish I had space and time to describe his establishment minutely, but must deny myself until some future occasion.

I had a long, dreary ride from Montreal to Toronto, over the Grand Trunk Railway. Let all jolly Englishmen who come to this country be sure to take that ride. It will settle them down in a way which they will not forget, besides give them a good lesson in forbearance. It is the roughest road I ever travelled over; the trains are always behind time, and very many cars lying alongside of the track here and there suggest frequent smashups, which are anything but pleasant to contemplate while riding along.

At Toronto I found Messrs. Notman and Fraser taking the lead, and doing the same splendid class of work as that done at the parent establishment in Montreal. Messrs. Ewing and Co. also have a fine establishment, as well as a fine house for supplies. They are also agents for the News, for the Ross lenses, and many other English materials. Mr. W. O'Connor is also a live photographer here.

At Hamilton, whence I proceeded from Toronto, I found two or three very creditable establishments. Mr. Inglis has just opened a branch, under the care of Mr. Jarvis, and Mr. J. M. Edy also prospers here.

From Hamilton I proceeded to Niagara; saw it in its winter garments, and also by moonlight and sunrise and then wended my way homeward to a huge pile of accumulated work, such as you only, being an editor photographic, can have any conception of. Yet I have gained many ideas and notions by brushing against so many good photographers, which I pray your readers may sooner or later become apprised of by the increased brilliancy of this correspondence.

Retouching Stump.—I must add a little squib, as you are partly responsible for it. A correspondent says: "When I wrote you a short time ago, I thought I had made two important discoveries; one of these I enjoyed for the space of three days, and then discovered that Mr. Wharton Simpson, in his "Notes In and Out of the Studio," for December, had made the same. The other, if old, will deprive me of all my laurels, and leave me as bare as the forests about me. One day, while retouching a negative, I bethought me of the stump used by the artists in monochrome twenty years ago, and the first trial satisfied me that I had found the best, and it is this: collect the finest grained and softest velvet cork, and, with a sharp, thin-bladed knife, cut it into

strips suitable for the porte-crayon; trim the end to a fine square point, and you have all that you can desire."

1 Curious Case.—Here is another curious thing which may be of use to you, from another correspondent, who says:—

"I enclose you two ferrotypes. The one, as you will see, a mass of fog or stain, similar to that produced in many respects by light, or an old plate-holder; the other, you will see, is perfectly clear.

"I will explain the cause of the trouble with the first plate. I am using an Ormsbee box with matched half-tubes. The cut-off was a little loose, and, being in a hurry, I picked up a sliver of wood, as I supposed, for a temporary wedge. That sliver was a bit of a match, and only had on it sulphur about the size of the head of a small pin. I hunted for the cause of the trouble for several hours, and finally smelled the faint odours of sulphur, scarcely perceptible at all; I removed it, and my work was as good as ever.

"The next plate is the one I enclose. It speaks for itself. It cost me about ten dollars to find out the trouble, as I could not send my customers away.

"I say, then, beware of the fumes of sulphur near your sensitized plates."

Our Exhibition.—I send you our plan of proceedings for the Exhibition. The affair promises to be a grand success, and we are indulging the hope that our good friend Mr. G. Wharton Simpson will be with us. He will receive a hearty welcome, be assured.* We are looking for some fine things from England, which are, no doubt, already on the way.

Indulging the hope that I may soon see you face to face, I am truly yours,

EDWARD L. WILSON.

PORTRAITS AND PICTURES.

BY JOHANNES GRASSHOFF.†

WHEN publishing my last paper upon this subject, now about a year ago (see PHOTOGRAPHIC NEWS, 10th June, 1870), it happened, either by accident, or from the fault of the compositor—or, shall I say, editor?—that at the end thereof the words "to be continued" were omitted. Fortunately this little circumstance did not prevent my friend Petsch from writing a sequel to my remarks (see PHOTOGRAPHIC NEWS, 30th September, 1870), and I now take the opportunity of thanking him for his valuable remarks upon the influence of individuality in portraiture. At the same time, I would ask permission to give a continuation from my own pen.

M. Quide has remarked that individuality in a portrait is a proof that the picture has actually been produced from the person who served as model, a circumstance which sitters are at times apt to question. No doubt this statement was made in reference to a tableau exhibited by one of thirty different photographs of one and the same person. Now, I have, it is true, employed all kinds of skilful dodges, Rembrandt and such like effects, in my work; but then, what will not the poor photographer do for the sake of art, for the fair sex, and for business? Many of my black-fingered colleagues have asked me how I manage to produce such pictures from many of the faces I meet with. My answer is very simple: I do not know myself; it is simply a matter of feeling.

Petsch has given us a very detailed and graphic account of the studio-life of photographers in large aristocratic cities, but he has forgotten altogether the existence of the provincial photographers in smaller towns, who are, it must be remembered, just as desirous of producing fine and delicate pictures for their customers. But how is it possible

* It is due to the kindness and generosity of our American friends, that we should inform our readers that they have not only given us a very hearty invitation to be present at the next Annual Meeting of the National Association, but have also asked our acceptance of a passage ticket to and from America. The exacting character of our duties does not, unhappily, permit us to take this pleasant holiday; but we cannot refrain from thus publicly recording their kindness, and our high appreciation of it.—Ed.

† Photographisches Mittheilungen.

to reproduce the leathery, or smoked-meerschaum countenances possessed by most of our country cousins in a soft and delicate manner. The unfortunate behaviour of the various colours which give such different results is here at fault, and the cause of all our difficulty. According to friend Petsch, it is always desirable that the nose, at any rate, should be tinted white, when it is not convenient that the whole mask should be coloured; with such dark brown features, however, it is necessary almost to lay on white oil colours, for white powder is often of no avail. We shall, indeed, always have difficulties of this kind to contend with, until some one has succeeded in improving the negative process, so that truer results may be obtained. Landscapes, as also reproduced oil paintings, give us particular proof of the injurious influence of colours. Every month almost, some new Lichtdruck or other similar process is invented; but as regards the improvement of the negative process, nothing at all seems to be done.

M. Petsch has, no doubt, had some experiences of this nature in his recent work before Metz, when depicting the fair-haired Germans from East Prussia and the Polish frontier. Some subjects of this kind appear more cautious in their photographs than in nature, and *vice versa*; and yet it is difficult to point to the reason of this. The cause, in most cases, lies in the colours of the face and the traits of countenance. How many ladies that dazzle one with their natural colours are reproduced in photography without being rendered full justice to! for the camera often only reproduces the form of the face, and sometimes even, as in brunettes, reverses the order of the colours. For this reason it is that one hears the oft-repeated complaint: "We have never been well taken!" and that general satisfaction is so difficult to afford. When persons such as these desire to have large vignette busts taken, I always produce the pictures on not too large a scale, and secure, on the same plate, a three-quarter portrait. Almost invariably is the latter preferred when the pictures are seen, the smaller head appearing the more favourable.

That there are persons, of course, specially designed to plague the photographer in his duties we must all agree (thin, hungry faces of grey-haired spinsters, for instance); and, with people of this kind, it is best to have recourse to some novel or particular lighting effect or prominent method of printing, whereby the attention is somewhat distracted from the portrait. It is often difficult, I know, to screen in this way the most marked parts of the picture; but, as far as my own experience goes, I have generally managed to do so successfully.

To one peculiar point in portrait photography I should like to call attention: Why are so many photographs printed in the vignette style? Is the general aspect of the picture thereby improved? In many cases the presence of stains and imperfections in the plate may be advanced as a sufficient reason for this manner of printing, but we see even the best kind of plates printed in this style, and it would appear, therefore, to be a comparatively easy task to produce vignette pictures.

When the portrait-painter or artist produces a sketch—a so-called study from nature—he makes but an outline of the background and bust, the sketch serving as the foundation for a real picture to be finished afterwards. But photography yields something more at the present moment than sketches; and, as we never see a vignette bust or three-quarter figure running about, it is surely more natural to represent the whole of the model complete. If two pictures are printed from the same perfect negative, the latter having been produced with a well-chosen and harmonious background, the one picture being plain and the other vignette, the former will, without doubt, be the more effective. And this is more true even with three-quarter portraits, in which the legs often appear to stand in water. We need, indeed, merely go to any exhibition of oil-paintings to see that in no case is a finished oil-picture painted in the form of a vignette.

A SUGGESTION FOR MOUNTING GLASS POSITIVES.

BY JOHN C. BROWNE.*

IN my experience, the greatest obstacle in preparing slides for the magic lantern is not the chemical manipulation required, but the mounting or preservation of the picture from injury occasioned by dust or scratching. The neatest form of mounting is that adopted by Mr. Langenheim, of Philadelphia, in which the positive and glass cover are cut circular, and inserted into a wooden frame of a size to fit any lantern of usual dimensions; but the risk of breaking the glass, and the time required in cutting the circles, is a serious matter to the uninitiated, and, taking the frames into consideration, somewhat expensive. The more general method of mounting slides is to cut the positive and glass cover $3\frac{1}{4}$ inches square, fastening the edges together with thin strips of black muslin, paper, &c., using a paste composed of flour, or what is known as bookbinders' paste; the latter is the best. Slides pasted with gum-arabic are not reliable, as the paper or muslin will crack off by heat and constant use, rendering the picture liable to injury. But this plan of joining the two glasses together by pasting is troublesome, and requires considerable time.

The method that I propose is to use a metal frame somewhat similar to a ferrotype preserver, but of heavier metal, finished plain, without any of the embossed or raised work that such frames have on the front side. The edges for turning over and protecting the two glasses need not be made wide enough to interfere with the picture when thrown upon the screen. Some months ago I wrote to a manufacturer of ferrotype preservers, asking him to stamp for me a few quarter-size frames in heavier metal, and stated that it was desirable to make the embossed work as smooth as possible. The result answered my expectations perfectly, as regards the frames being strong enough to preserve the picture, but the size was not desirable; also, the embossed work (although lightly stamped) prevented the picture sliding smoothly. As a suggestion, I propose that frames be made $3\frac{1}{4}$ inches square, and stamped in a plain die. Pictures can be rapidly mounted by the use of this frame, and the labour of pasting entirely avoided. When exhibiting pictures, a wooden frame can be used, having a square cut in the centre, which will bring each picture into the exact position desired on the screen, and will require but little change of focus.

PHOTOGRAPHY AND THE STEREOSCOPE.

BY JOHN HENDERSON.†

THE time which has elapsed since stereoscopic photography ceased to be a novelty, and the copious manner in which the subject has been ventilated, almost demand some apology for again bringing it forward. I have, however, the less hesitation in doing so as I conceive that the matter has latterly received less attention than it deserves; that it is a branch of photography especially fitted for amateurs; and that as the stereoscope received its impetus mainly, if not entirely, owing to its early connection with the infant art-science of photography—so, as long as an interest is felt in the phenomena of binocular vision, as long as it is conceded that the photographic views of most objects are seen more vividly and naturally in this than in any other manner, and while, as an educational instrument, the stereoscope can be shown to have value, so long may we derive recreation and advantage from the practice of stereoscopic photography.

I need scarcely remind you, at the outset, that from a very early period the fact was noticed that each eye saw an object under different aspects, which conveyed to the brain the impression of one solid. Euclid (300 B.C.) knew that each eye in one view saw different pictures; Galen, in the

* Philadelphia Photographer.

† Read at a meeting of the Liverpool Amateur Photographic Association.

second century, expresses the same idea more clearly. Writing in the sixteenth century, G. Baptista della Porta further illustrates the theme. Two pictures at Lille, executed about this by Chimenti, were, as recently as 1862, thought to have been done in illustration of the binocular theory; but the close resemblance of the pair is not now believed to have had any such intentional origin.

In the seventeenth century a learned Jesuit, Francis Aguilonius, wrote so fully on the subject that it was scarcely again taken up till the present century, when Professor Elliott and Mr. Wheatstone, independently it would seem, gave more tangible expression to the idea by the construction of stereoscopes in different forms. In 1823 Mr. Elliott wrote an essay "On the Means by which we Obtain our Knowledge of Distances by the Eye." About 1834 he conceived the idea of an instrument whereby two dissimilar pictures might be combined. In 1838, at the meeting of the British Association, at Newcastle-on-Tyne, Mr. Wheatstone contributed a paper, which he had prepared shortly before for the Royal Society, on the "Physiology of Vision," and exhibited a reflecting stereoscope. In the following year, 1839, Mr. Elliott, unaware of this fact, exhibited at a meeting of the Polytechnic Society of Liverpool, then just formed, an "ocular" stereoscope, consisting simply of a deep box, destitute of any optical arrangement, at the bottom of which were shown two moonlight views about two and a-half inches distant, representing the right and left hand aspects of a landscape in three planes of distance, and which combined on examination. Later still, Mr. Walter Hardie, of Edinburgh, invented an ingenious modification of the reflecting stereoscope, which, while compact, was capable of exhibiting large-sized pictures placed above each other, and viewed through reflecting prisms after the manner of the camera lucida. In the years now under review the Daguerreotype, Talhot-type, and kindred processes were brought out; and just previous to the era of collodion Sir David Brewster had worked out the idea of his lenticular stereoscope, which he first exhibited at the meeting of the British Association, at Birmingham, in 1849.

Some few instruments were made in Scotland, chiefly at Dundee, but here they failed to attract the attention of those most interested. In Paris the inventor was well received, and on the 30th December, 1850, M. Duboscq showed the instrument to the Imperial Institute of France, and caused a quantity of Daguerreotype views to be taken, which, with a number of stereoscopes, were first publicly shown in England in 1851. The publicity which the Great Exhibition of that year secured for them led to their universal popularity in this country, to which the manufacture rapidly extended. The stereoscopes of that day scarcely differed from those now ordinarily in use, which, however well adapted for Daguerreotypes, where the illumination has to be carefully controlled, or for transparencies, fail to admit sufficient light to paper prints, and the chief advance has been towards improvements in this direction. In the improved achromatic mirror stereoscope of Smith and Beck the lenses revolve to assist eyes otherwise imperfect, or to correct errors in the mounting of the prints.

The first pictures for the lenticular stereoscope consisted of drawings of geometrical solids, of lithographs from calotype pictures, of laborious hand drawn binocular pictures, such as Cruikshank's "bottle" series, and of Daguerreotypes. When collodion had prepared the way for the easier and cheaper reproduction of paper prints or glass transparencies, a "stereo" mania was aroused—a *Stereoscopic Magazine* was started, which came to an untimely end, and a Stereoscopic Company, which survives. Among the earlier aberrations from truthfulness, "ghost" effects may be classed. Photographs of an unworthy character appeared later on, though it is not easy on this or any other grounds to account for the comparative neglect into which stereoscopic photography has fallen.

It is difficult to teach the uninitiated how to combine stereoscopic views without a proper instrument, in which

the lenticular prisms or semi-lenses magnify the images, and also refract the two pictures towards a common centre. In ordinary vision the two eyes converge towards a point more or less remote. In combining views without the aid of a stereoscope the eyes look in parallel directions, or even diverge. Where the two views have been omitted to be transposed, they are similarly combined by the operation of squinting.

In viewing any landscape or object, the attention, as already stated, is always concentrated upon a point in any one plane of distance, and the eyes insensibly judge of the distance of such point by the angle, more or less acute, which is included by the convergence of the optic axes. This is precisely what occurs in the examination of a stereoscopic picture taken and viewed under proper conditions; and it is the wonderful illusion then practised, when our "eyes are made the fools of the other senses," that constitutes the charm of the stereoscope.

Complementary colours presented to each eye in the stereoscope, produce by combination a dirty white. In colours of differing intensity, the most intense will assert itself to the exclusion of the other. Where the intensity is similar, they mix as they would on a palette—yellow and blue forming green, and so on—though these results are not always obtained without an effort of volition.

In our ordinary vision of surrounding objects it will be found that one eye sees, so to speak, while the other presents the relief of the thing seen to the mind; that is to say, if we sketch any object, the relation of its parts to the whole, and of the whole to surrounding objects, will be found, on the completion of the sketch, to have been the view as presented to one eye only, as may be proved by comparing the picture with the actual view as seen by the right eye, while the left is closed, and *vice versa*. The truth of this idea may be further illustrated by viewing the reflection of surrounding objects in a mirror, when, if the eyes are alternately closed, it will be found that the "miud's eye" has been viewing in relief the images as represented on the retina of one eye rather than those seen by the other.

In viewing a near object especially it must be obvious that the perspective, and even the relative, size of the object, as presented to the eye nearer to the object, must differ from that presented to the eye further from it. Practically, this is not perceived, and the solution of the difficulty is that all parts of the object, &c., beyond the point under view at that moment, are really seen double on other portions of the retina; but the altered direction and convergence of our vision are acts so rapid and involuntary that, under ordinary circumstances, the fact is not noticed.

I must now pass on to considerations of a more practical nature, by giving a few hints in connection with the production, mounting, and viewing of stereoscopic pictures, in so far as they differ from single photographs. As it is desirable that a large amount of subject should be included in the small space at command, the use of short-focus and wide-angle lenses will be often advantageous, though, in this respect, great caution and judgment are needed.

Softness and detail being more important than brilliancy, very full exposures should be given. Natural skies may be taken on a second plate before removing the camera, and printed by combination. More than usual care should be taken in the focussing, and the same may be said of the preparation and development of the plate, as any defect tells its own tale.

A good foreground is a necessity in all cases to give the proper relief, and where it cannot be had, and the principal object is at a considerable distance, the two views may be taken from points much wider apart than three inches.

The prints for mounting, if including subjects of interest near the margin, may be cut three inches broad, but leaving the corresponding distant points about two and three-quarter inches apart when mounted; otherwise the corresponding points may be two and a-half inches apart, and the prints cut larger in proportion—say two and three-

quarter inches. This method bears some analogy to that which occurs when viewing any object of less than two and a-half inches in diameter, and it is justified by the practice of some of our best authorities. For use with the stereoscope of Messrs. Warner and Murray, they may be cut as high as five and a-half inches.

The prints may be rapidly and neatly cut by a knife upon a glass plate, using two rectilinear glass guides, one seven and a-half by five inches, and the other three inches square. Let A be the right and B the left-hand view, as yet attached and untransposed. With the long guide cut the base of both views and the left of B, from which base, with the square guide (which is henceforth used) cut the right of B at the proper distance, then cut the left of A, upon which place B, and, having marked off the width, cut the right of A. Superimpose both prints, and cut both tops together. All this is done in less time than it takes to describe, and the result is two rectangular prints exactly alike in size. By doubling up the upper portion of the prints, the four upper corners may be rounded by hand with scissors, which sometimes gives a finish, and removes that which it is not desirable to retain. Before commencing to cut the prints, the right-hand view should be marked at the back. The ordinary mounts being rectangular and twice as long as broad, one may be used to draw a pencil line, dividing the face of the other into two squares.

After mounting, the prints should, if possible, be rolled ho.

The finished pictures, to be truthful, should be seen in the stereoscope at a distance from the eyes equivalent to the focal length of the lenses employed to produce them in the camera; and if the lenses in the stereoscope are of too great focal length, and especially if the views have been taken with wide-angle short-focus lenses, then the innermost edges of the last named lenses may be used themselves with advantage.

It is further important that the very inclination at which the camera stood at the time of exposure should be preserved in viewing the finished picture. Several views now shown, taken vertically, and in other unnatural positions, bear out this assertion.

Architectural views—including vertical lines at the edges, and taken with short-focus single lenses, but which lean slightly—will be found to assume their proper position when viewed in a stereoscope whose lenses have a high magnifying power, and are duly corrected. If the camera, however, has been "tilted" even slightly, the picture will not then represent correctly the height of the original.

Were I inclined to dwell at length on the inducements which this branch of our art-science holds out to the amateur, I might speak of the compactness of the apparatus, of the adaptability of this size of view for lantern subjects (in which case, indeed, two dissimilar views may be taken on the one plate), of the charm of instantaneous views, and of the ease and frequency with which views suitable for the stereoscope present themselves. I might further point to the attention which some of our best professional landscape photographers have given to it, and to the hints and models which their productions afford. I might likewise point to the field which it presents for the delineation of low-power microscopic objects. But I have already exceeded the limits which the subject, perhaps, demands; and, if I succeed in reviving an interest among any of our members in the study and practice of stereoscopic photography, my object in bringing forward such an old theme will have been attained.

THE "EDINBURGH REVIEW" ON PHOTOGRAPHY.*

AFTER a description of the heliotype process, the writer remarks:—

"Heliotype is fitted for all kinds of work, and does not require special negatives, as the picture is not reversed in printing. The pictures can be printed in any colour;

* Continued from p. 211.

and, indeed, the painter seeks a point even in ordinary prints, of giving two things to the picture—one for the dark shadows, and ordinary black ink, and another is a golden hue, for the better tone—and the effect is very good. The progress in Italy this process are very beautiful. The portraits of Vasdyka and Reinhardt in recent numbers are admirable examples of its power of rendering, with perfect clearness, the vigour and depth of the original paintings; while the rendering of Mount St. Michael, Northam, is a faultless specimen of rendering this grand scenery. This specimen of work we saw in the gallery of the portrait-gallery in the British Museum, and we have reason to believe that the keeper himself looks upon this specimen as a very worthy result of the new art. Heliography promises to give to literature what has been so long desired: printed transcripts of photographs at a cheap rate. The method of working and the cost of producing it is so small that it bids fair to invade all the cheaper forms of literature, and to reproduce for us drawings from various sources of inferior wood engravings and lithographs.

An account of lithography at Southampton Establishment follows, and its use for Ordnance survey maps, &c., upon which the writer observes:—

It was at first doubted that the reductions made by means of photography were sufficiently accurate, and in 1835 Sir Richard Neville stated in Parliament that the plans so reduced were not to be depended upon. Whereupon a committee was appointed, of which Sir Robert Mitchell was chairman, to report upon their accuracy as compared with plans reduced by the old process, and upon the saving effected by the photographic process. The result was that the committee stated that the greatest deviation in any part of the plan from perfect accuracy does not amount to one four-hundredth part of an inch in the angle of the rectangle, and that the saving effected is not incommensurate, and that the saving already effected has been £1,000 per annum, and is now more than £20,000 a year.

After some observations on photolithography and astronomical photography, the article proceeds:—

With regard to ordinary photography seems to be giving its powerful aid to medicine and its allied sciences. Dr. Sæverien, in a paper on the influence of the heart examined by the movements of respiration on the circulation of the blood, gives a plan of registering the rapidity and volume of the human pulse by means of the pulse-machine, which is made to record itself by a series of spring pens upon sensitized paper. This may be considered rather a curious than a useful application of photography, but it is eminently necessary to say that his aid is of the greatest value to the physiologist, the physician, and surgeon. The numerous changes made in the aspect of wounds are had a faithful record by smaller means, and the splendid success in the possession of the Royal Medical-Chirurgical Society is a testimony to the value placed by the profession upon this method of illustrating their cases.

The power of the sun's pencil in giving intense and subtle indications of expression in the human face has made its valuable testimony power in psychological medicine. The power of words to express certain types of insanity is feeble as compared with the whole aspect of the patient and the expression of his face, these the photographer can give with unerring certainty. Dr. Conroy discovered a valuable series of papers on the pathology of insanity by photographs of the different types taken by Dr. Deane from his asylum, and is at all times anxious they are truly valuable.

It has been suggested that before it is too late, the art should be made subservient to recording the types of the various races of men that are slowly disappearing as civilisation advances. This would be a worthy occupation for the Ethnological Society. Dr. Livingstone, we know,

received instructions in the art, and we may hope that he will bring us home portraits of the strange tribes he has been made acquainted with during his long sojourn in the interior of Africa.

Dr. Forbes Watson has made us acquainted with some of the leading types of India, but how little do we know of the infinite varieties that exist in that vast country, and in Asia generally! The physical aspect of man is a subject photography alone is capable of correctly illustrating.

With respect to the influence of the evil passions upon the physical eye, we have some record in the portraits of criminal prisoners. The prisoners of the criminal prisons furnish copies of these to the head station in Scotland Yard, and a valuable gallery of faces, as a rule, it presents. There is a photographic apparatus at the chief police station at Scotland Yard, and it was used some years since for the purpose of taking portraits, especially during the Feman excitement, but it has not been used since; in fact, there is no legal warrant for taking a prisoner's likeness, and it more than sometimes where this portraiture has been attempted it has been successfully resisted. Photographs are often a most valuable aid in discovering persons wanted, but they are nearly always furnished by other persons to the police.

A very singular case of a thief who was choist with his own portrait, occurred some little time since at the West End. A lock-off-five man, whose time had expired, called upon a photographer in the High Street, Kingsway, and managed to walk in the waiting-room, to pick up a lock and steal £10 in gold and silver. He remained for some time, and the photographer going to him to ascertain his business, he said he had an order for some card portraits, and he wished to be shown specimens, which was done. The photographer, unaware of his loss, as a reward for his trouble, expressed a wish to take his portrait, so that he might present him with several copies. The prisoner was not at all anxious to submit to the process, and it was thought that the likeness was worthless; as lock would have it, it turned out a particularly good one. The loss of money was discovered, the photo was handed over to the police, and by its aid, the thief was discovered and apprehended by an officer a few weeks after in Brompton.

The law has obtained, through its instrumentality, a witness to fact which it is difficult to gainsay. There is no cross-questioning such evidence. In cases of boiler explosion and accidents to machinery, and even the damage done to vessels by collisions at sea, the silent evidence of the signature is sufficient to settle many a disputed point; and not long since a lawsuit, in which Earl Spencer was one of the litigants, was decided by a photograph of a public road and a garden wall, which settled a point of disputed boundary.

Not the most extraordinary piece of legal evidence we have yet heard of occurred some time since in Australia. A gentleman named Black went with a surveyor to examine into the particulars of a certain mine claim, when he was suddenly seized by some rascals (supposed to be in the pay of the other party), stripped, smeared with tar, and, far worse of feathers, was ornamented with straw, wool, and other rubbish. When he managed to escape from his persecutors, instead of returning to get rid of his horrible ornamentation, he determined to take a note of it at once, and forthwith proceeded to a post-grayer, where his likeness was taken in this extraordinary costume, and with this evidence upon him, he proceeded to his lawyer, and laid the damage at 2000 dollars, which he ought to have obtained if he had not.

The War Office has taken advantage of the new agent to obtain pictures of all the modern battle-fields, and especially of the strategic positions and of the fortifications. We see such in records of the war, both of the Crimea and that of the Abyssinian expedition. The power of highly sensitive paper in giving pictures of explosions is of

great use to the Corps of Engineers. The height and the breadth of torpedo explosions are thus made patent to the eye; the powers of projectiles, as shown by the impact of shot in armour-plates, are also graphically rendered by the light-picture. It is the practice now to photograph all patterns of stores supplied to this department.

"If, in conclusion, we refer to the aid photography will be to art itself, we shall not have mentioned one of its least claims upon public favour. Those who have visited the annual exhibition of the Photographic Society in Conduit Street cannot fail to have marked the instruction the artist may obtain from these moments of nature arrested and fixed by the silver print. The grand sea-views by Colonel Stuart Wortley, in which not only the clear naked wave is painted by the pencil of light as it is rolling over, but the very drifting mist-like spray upon its crest as it dashes upon a rock. Who can estimate the value of such momentary records of details of nature to the artist—movements that would otherwise fade from his memory? How dignified even the commonest photograph is made by the delicacy of light and shade it presents. Every head has the power of a Vandyck or a Titian. Its teaching power in this respect is undeniable. Year by year the familiarity of the public with the works of this splendid draughtsman will make the acceptance of slovenly drawing impossible. In the art of design the facilities of the sun-picture cannot fail to be appreciated and taken advantage of. Mrs. Cameron, in some of her poetical groups, and her fine examples of form, has taught us its power of fixing grace upon the canvas [?], and the varying forms of human expression. The same flash of light which registers the drifting foam can seize the emotion of the human soul as depicted upon the countenance. Far be it from us to say that the gifted artist should work from such reflections as these, instead of going direct to nature, but their supplementary aid cannot be undervalued. They will not take the place of the poetical eye and skilled pencil, but they will afford excellent records of needful details and of fugitive expressions, to be stowed away for future use. The public knows nothing of the folios of sketches the artist keeps by him. These are the bricks, so to speak, out of which the finished picture is built up. Much of this work the photograph will do for him, leaving his mind free for the higher art of conception and design.

ON PHOTOGRAPHY IN THE PRINTING PRESS, BEING A DESCRIPTION OF THE WORKING OF THE HELIOTYPE PROCESS.

BY ERNEST EDWARDS, ESQ., B.A. (CANTAB).*

I HAVE NOW to describe the heliotype process. The action of hot water on gelatine is to dissolve it; the action of cold water is not to dissolve it, but to fill up the pores and swell it up, just as in the case of a sponge; and as, after exposure to light in presence of a bichromate, hot water will no longer dissolve gelatine, so, after exposure, cold water will no longer expand it—can no longer penetrate the pores. The light has, in fact, had the effect of closing the pores, and thus rendering the gelatine waterproof. If, then, we cover a glass plate with bichromated gelatine, and expose it to light under a negative, there will be certain parts of it which will be completely waterproofed, having the pores completely closed by the light; certain parts—the half-tones—which will be partly waterproofed, having the pores partly closed; and certain parts where the condition of the gelatine will be unchanged. Now, if we steep this plate in cold water, some portions of it—those where light has not acted—will absorb water, and others will refuse to do so, having been waterproofed by light. If we take grease and rub it over the plate, the result will be that where the pores are full of water—that is, where the light has not acted—the grease will not touch the gelatine; but where the light has acted the pores are closed, there is no water, and grease

attaches itself readily. Where the light has partly closed the pores, the small quantity of water absorbed does not prevent a small quantity of grease attaching itself. Lithographic ink is simply grease to which colouring matter has been added; and a lithographic roller charged with such ink, and rolled over such a plate, speedily reveals the light-produced image.

This method was discovered by Poitevin, and even patented by him, as early as 1856. But I doubt if he understood its true principle, for he appears to have considered that the action of light converted the gelatine into something of a waxy or resinous nature, which, on that account, took the greasy ink. However this may be, no results were produced by him, and the method in that form did not come into use. The practical difficulties met with in attempting to work it arose first from the spongy and delicate nature of the gelatine film in those portions where light had not acted, and, next, from the difficulty of obtaining intensity in the inking and sharpness in the image, and from other technical obstacles. Bearing in mind the character of the image on the gelatine, it will be understood that those parts of the gelatine not acted on by light were in much higher relief, from the presence of the water which they absorbed, than those parts which, having been acted on by light, did not absorb water. But it is the depressions which take the ink, and the walls on each side of the depressions prevented the roller from reaching them; and again, it is the depressions to which the pressure must be applied, in order to allow the paper to pick up the ink. It was found that when the requisite pressure was applied the gelatine was speedily destroyed, more especially as the description of pressure employed was that used in lithography, where the force is a scraping one over the surface of the stone.

MM. Tessie du Motay and Marcelal were the first to make use of Poitevin's method in any way commercially. They attempted to provide against the swelling of the unaltered gelatine by using a very thin layer of it, and only printing such subjects as gave but slight contrasts. The results produced, though sadly wanting in vigour and firmness, were, at the time (1868), considered satisfactory; but it was found that, after a very few impressions, the gelatine was crushed, and became useless, more especially as the film, to be at all manageable in inking, had been made very thin.

Herr Albert, of Munich, next produced some results by a similar method. We do not find that his plan of working has been published, but it is believed to be somewhat as follows:—

Instead of a lithographic stone, a glass plate is employed of considerable thickness. On this is placed a layer of gelatine and bichromate, which, when dry, is hardened all over by exposure to light; on the top of this is placed a second thin coating of gelatine and bichromate, and this is exposed to light under a negative. In this manner a compound printing film is obtained, having the necessary degree of thickness to stand a certain amount of wear and tear, whilst, from its construction, the difficulty of the swelling of the gelatine is, to a great extent, got over; the plate is then inked, and printed in the usual way. Some of the results produced by Herr Albert are most beautifully soft and delicate, but the whole are wanting in strength and robustness, and the process seems unsuited for the production of lines or subjects where firmness and strength are required. The films, moreover, are only mechanically united, and are very liable to injury in working, whilst the use of glass plates as supports, from their liability to fracture, introduces an element of uncertainty into the process that is very undesirable. But the results produced were so fine that, on seeing them, I was at once convinced that in that direction lay the future of permanent photographic printing.

There are many ways of closing up the pores, or of waterproofing gelatine. We have seen that the action of light in presence of a bichromate will do so completely. Admixture with alum, more especially chrome alum, will

* Continued from p. 210.

do so as completely without the action of light; and, after such treatment, the gelatine is converted into a tough, tawny, insoluble substance like leather or parchment, capable of standing an apparently unlimited amount of rough usage. In the course of my experiments I discovered that gelatine might be converted into this substance, but that it still retained its property of being acted on by light in presence of a bichromate, and of receiving and refusing greasy ink. The merest trace of water is sufficient to secure the repulsion of grease; and in chrome alum we have the means of closing up the pores of gelatine to any desired extent, and under the most complete control. Here, then, was a most important point gained. Instead of having to deal with a soft spongy mass of gelatine, so swollen with water as to be useless, I secured by this means a tough film of sufficient thickness, which, while it would absorb sufficient water to repel grease, was yet so little swollen as to present no difficulty in inking or printing—a film which was sufficiently dense to give perfect firmness of line, with entire freedom from the grain which is sometimes seen, and which was so tough that 100 or 150 impressions might be pulled from it without the least loss of quality. But I found, in practice, that when these films were used on glass supports there was great difficulty in getting contact between the gelatine glass plate and the negative during exposure to light. The slightest inequality in the surface of either negative or gelatinized glass, the slightest speck, prevented contact, so that line subjects were practically unobtainable, and many plates were failures on this account. Moreover, but a comparatively small amount of pressure could, with safety, be applied to a glass plate in the press; not nearly so much, indeed, as was desirable, and even with the greatest pains fractures were of frequent occurrence. To obviate these difficulties I devised the following method:—

The solution of gelatine and bichromate, to which has been added the requisite amount of chrome alum, is poured on to the surface of a carefully levelled glass plate, and dried. But the surface of the glass plate has been first rubbed over with a little wax, so that when the film is dry it is readily detached. We then have a film only, not a thick glass plate, to deal with, of the thickness of stout paper, and just as manageable. With this film there is no difficulty in getting contact with the negative, and we are able to obtain the most intense sharpness. There is no risk of breaking the negative, and the management of the film is as easy as that of the paper on which photographs are ordinarily printed. A piece of such a film is placed in contact with a negative, and exposed to light, the sufficiency of the exposure being indicated when the whole details of the picture are apparent. The next step is to attach it to the support on which it is to remain during printing in the press. For this purpose, a plate of metal is taken, such as zinc or pewter, and the exposed gelatine film is placed in contact with it under water. We have now to get rid of the water which is between the film and plate. This is done by means of a tongue of india-rubber let into a strip of wood—just such an instrument, in fact, as is used in cleaning pavements in dirty weather, and which is known by the name of the "squeegee." This instrument is passed sharply over the surface of the film, and squeezes out the water between it and the metal. Then the absorbing property of the gelatine is brought into play, and the film is attached to the plate by exactly the same force that a boy with a leather sucker is able to lift a stone of considerable weight; that is to say, by virtue of atmospheric pressure. The plate, with its printing film attached, is stepped in water for a sufficient time to soak out the superfluous bichromate, so as to prevent the further action of light, and is then ready for printing at the press. Instead of a glass plate, of necessity fragile, we have now a printing film to which we may apply, without risk, any pressure we please, and which, when the requisite number of impressions have been taken from it, may be removed from its metal support, and stowed away for future use. At any time it may be again laid down and

the printing proceeded with; and, as it is of a bulk but little greater than a sheet of paper, there is no difficulty in storing. I do not hesitate to say that this method of transferring the films increases the value of the process ten-fold. Having obtained our gelatine matrix on its metal support, we now come to the inking and printing.

(To be continued.)

STRONG AND WEAK DEVELOPERS.

BY ELBERT ANDERSON.

[Mr. Anderson continues his hints on exposure and development.]

M. I believe I understood you to say that an insufficient exposure could not be remedied by strengthening the developer.

A. Yes, I said so.

M. And I believe you further said that you keep a strong and a weak developer, which you mix together as occasion calls.

A. I said that also.

M. What, then, is the nature of the circumstances which require this change of developer?

A. I do not know whether you are aware of it or not, Mr. Marshall, but you have now approached a subject of the greatest possible moment, and I advise you to listen well to what I am about to state. Now for another experiment. I will coat this plate and expose it twenty seconds, on a certain subject, and develop with a strong developer—that is, strong iron solution.

M. This comes up very quickly.

A. I will now coat another plate and expose on the same subject the same time—twenty seconds—and develop with a weak solution.

M. This comes up much slower; is this the only difference?

A. The negatives are both fixed and washed; come, look at them.

M. Why, bless my soul, what a difference! This one is thin and flat, without much contrast, and was made with the weak developer, of course; whilst that one is strong, with much more contrast, clearly showing the effect of a strong developer.

A. My friend, you are all wrong. It is just the reverse.

M. What do you mean by just the reverse?

A. The negative with these strong contrasts was made with the weak developer, and the flat one was made with the strong developer.

M. Is that so? How do you explain this seeming paradox?

A. Mr. Marshall, I assure you, that when you see two such effects and opposite results produced with exactly the same exposures, it cannot but strike you most forcibly that, of all the manipulations of the negative, nothing can exceed in importance that of the development. It is the very key of the whole making of the negative. Talk of the secrets of the dark room, this is the secret! I showed you some time back the effect of strengthening a negative. I showed you that the second development (strengthening) was in proportion to the first deposit, and I will now show you that the first deposit is in proportion to the strength of the developer. The stronger the developer is in iron the arid being the same in both cases, the more rapid the development; this you already know; but you may not know that with a weak developer the reduction is so slow that the lights, *i. e.*, the most impressed parts of the plate appropriate to themselves the silver as fast as it is reduced, and it is not until they are overcharged that the shadows "get a show"; thus the negative has strong contrasts. But with a strong developer the silver is reduced in sufficient quantities to supply both, the shadows as well as the lights, and if too strong, the shadows receive the deposit almost as fast as the lights, making the negative flat. Now you have only to still further increase the iron, when the reduction will take place so rapidly that the impressed image has not

sufficient time to dispose of the silver, which is reduced over the whole plate.

M. Result, a healthy old fog. Why, I had no idea that so much depended upon the development.

A. It is of every consequence; and here it is where you want your wits about you. It requires the utmost care, good taste, and judgment on the part of the operator. It is far better that you over-expose ten seconds than under-expose one half a second. The former can, in a measure, be remedied; the latter is hopeless. I have shown that too rapid a reduction will "fog" your negatives, and I shall show you later that a too slow development will produce the same effect.

M. Any other little suggestions on development? The smallest favours thankfully received, larger ones in proportion.

A. Sec, here is Miss Aurora Cynthia de Brown. I shall make two negatives of her: one in her pretty black velvet hat and feather and cloak, and the other in her white dress and laces. Now, if I use the same developer in both cases, I must give twice the exposure in the black suit.

M. That's what I should have done; but, gathering from what you have said just now, I suppose I had better give nearly the same time, and modify my developer.

A. Assuredly. In order to get fine detail in white drapery, give a full exposure and use your developer rather weak; keep your wits about you, and do not over-develop; and when she sits in her black suit strengthen your iron, and "look sharp."

M. Good; I'll try it.

Correspondence.

THE GRAPHOGENIC.

SIR,—When I ventured to point out what I considered defects in a new and much lauded system, I little expected to be assailed, unless by those pecuniarily interested in the Graphogenic, and must beg the favour of a word in defence, although I dislike occupying so much valuable space in your pages on a matter that has become somewhat personal.

Mr. Edwards has more than once objected to my adopting a *nom de plume*. Did I make an attack upon him, I should sign my name in full. As I have seen him but once, when he very kindly explained his Patent Printing-Framo, there is no reason for any animus against him, and it does not exist as "Justice" insinuates. I cried out against the high price Mr. Edwards charged for his Patent Frames, and he soon after gave up the two guineas for licence to use them. I look upon that as a recognition of the justness of my complaint, and not in the light of a defeat. Neither Mr. Edwards nor his partisans attempt to deny the defects I point out in the Graphogenic, but, like so many bulls, blindly charge at me.

Mr. Edwards asks me if I have tried his new developer, or want to break a lance with him? "Justice" says it is wrong to point out objectionable features in anything new, forsooth, because of the loss to the pateutee (!), and if I don't like it I can let it alone. "W. L." fails to be funny, and wants a description of what he is pleased to call my *invention*. "Scrutator" is simply coarse and offensive.

Now, I do not want to break lances with anybody; but to Mr. Edwards, and those who propose to "Graphogenicate," I beg to offer an "idea" which may be new, and will do away with one of the defects I alluded to. Have a slight frame of suitable size made, with a sliding plate of glass for a cover; in the centre of this plate drill a hole of sufficient size to pour the collodion through on to the cleaned plate beneath, the surplus collodion running into a reservoir at one corner; the frame, with plate, is now placed over the india-rubber bath, the plate dropped into its place, and sensitized in the usual way before transferring to the dark slide.

If "W. L." has experimented long and largely with tents, and has been a dry-plate man for twenty years, his experience would be valuable to many of your readers who, like myself, too poor to pay for expensive tents which do not meet our wants, set about making one for ourselves. I do not claim any superiority for my "baunting," but I have got what I cannot get at a

photographic warehouse. Rather than stagger, loaded like a porter, with a 10 by 8 or 12 by 10 camera and "Graphogenic" one mile, I would wheel my apparatus, with its conveniences, five miles.—I am, sir, your obedient servant,
INGENIO.

KEEPING PLATES MOIST AFTER DEVELOPMENT.

DEAR SIR,—Will you have the kindness, in your "Answers to Correspondents" in next week's NEWS, to inform me what your Indian portraitist, in p. 206 of this week's NEWS, refers to when he speaks of "Robinson's delightful process, the syrup?" I cannot quite make out whether, in the case referred to, the writer uses the syrup as a preservative *before* exposure, or whether it is applied after exposure and development, to keep the plate moist for intensifying after it is brought home. I suspect that a solution of vinegar and treacle boiled together would answer extremely well as an application to plates after development in Mr. Edwards's Graphogenic Apparatus, and obviate the necessity of keeping the film moist by the use of a metallic box. Perhaps, however, it might be better to employ a boiled solution of loaf sugar, with a dose of strong, colourless acetic acid, as likely to diminish the tendency to reduce the silver in the film, which the application of the more impure saccharine matter might possess.

I have very great faith indeed in Edwards's Graphogenic invention, the action of which I am going immediately to test by actual work.—Yours very faithfully,
W. L.

[The allusion in question is to the use of a mixture of equal parts of golden syrup (molasses) and water applied to the plate after development. It at once arrests development, and keeps the plate in good condition for subsequent intensification and fixing. The action of molasses in regard to reduction is of a singularly retarding nature; added to the iron developer it is one of the most powerful restrainers we know.—ED.]

PHOTOGRAPHY WITHOUT DARK ROOM.

DEAR SIR,—I find by an article by Mr. B. J. Edwards upon a new apparatus for working the wet process without a tent, that we have been working in the same direction. The contrivance I use is similar to Mr. Edwards's in principle, but widely different in detail. The idea struck me nine years ago through a friend in trouble. He had a commission for a picture larger than he had a bath to excite the plate in. He came to me to know whether I had got one. I had not. A thought struck me that he might do it in the tray he used for exciting paper in. I told him to try it. He did so to his satisfaction, so he told me.

I then thought of turning the idea to account for out-door work. I made a dish or tray of wood, and one to fit over it to hold the plate, and to serve for a dark slide as well. I thought I had made a great discovery. So I had, so far; but I then found I wanted the principal part, which was a tray to develop the picture in. I made one; and when I went to develop the picture I was in a fog, for I could not see when it was developed enough. I tried to find something so that I could see, but could not succeed, so I laid it by, and tried several schemes quite different to the first one, but with the same result; so I gave it up for three or four years, but still believed it was to be done. I tried several times after that, but could not find out what I wanted, so I laid it by again, and other things occupied my attention, and I quite forgot all about it until I saw a contrivance by Mr. Barrett, which brought it to my mind again. I worked my brain again to no purpose, so I laid it by again, but still kept thinking, till at last I saw the very thing I wanted in the PHOTOGRAPHIC NEWS, which made my heart leap for joy. It was a description of a developing tray with a glass bottom by Mr. England, for which I heartily thank him, as he was the means of pulling me out of the mire which I had been floundering in so long.

I should have sent a description of it at the time, but being called away I have had no opportunity since of doing so; and now Mr. Edwards has got his out and patented I do not know what to do, as he may think I took the idea from him, and want to do him an injury by infringement upon his rights. I have not seen his, nor heard of it till I saw the article in the NEWS. My only object is to help others, if I can, without doing any harm. If you will give me your opinion upon the subject in the correspondence column you will oblige your humble servant.
E. MARSHAM.

[We shall be glad to see a detailed description, if possible, with diagrams, of our correspondents' contrivance, and we can

then better form an opinion. If it be the same as that of Mr Edwards, even with admitted priority of invention, it would infringe the patent.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF LONDON.

THE usual monthly meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, the 9th inst., Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a previous meeting having been read and confirmed, Mr. A. Johnston, of Wiek, was duly elected a member of the Society.

The CHAIRMAN announced with regret the continued illness of Mr. Hughes, and the consequent indefinite delay in the production of his paper on the carbon process.

LORD LINDSAY exhibited the ingenious apparatus attached to his telescope for exposure of a number of plates in succession to the image of the sun during the eclipse.

After some conversation, and a vote of thanks,

Mr. ERNEST EDWARDS, B.A., read a paper on the Heliochrome Printing Process, which was identical with that read before the Society of Arts (see p. 224). A number of fine specimens were exhibited, illustrating the capacities of the process, and the mode of printing was practically demonstrated, prints in different stages being produced and exhibited to the members. A print with little half-tone, but vigorous blacks and whites, as produced by a stiff ink; a print with much half-tone, but no vigour, produced by rolling only with thin ink; and then a perfect print, rolled with both inks, gave much interest to members.

In the course of conversation on the subject,

Mr. BEDFORD asked if it would be possible to produce a set-off on a stone, in order to produce tint stones for prints in two or three tints, as such a capacity would give the process great value for certain kinds of reproductions.

Mr. EDWARDS replied that all facilities of that kind possessed by lithography were available with the process.

After some further conversation, and a vote of thanks, the Chairman announced that Mr. Edwards had presented examples for distribution with the Society's Journal, and that each member present would also be presented with a specimen.

The CHAIRMAN also called attention to some fine cameo vignettes by Mr. G. Hooper, and to the specimens of the photographs of the Amateur Photographic Society around the walls. He also called attention to a number of useful contrivances for aiding manipulation, exhibited by Mr. Whiting.

Dr. MANN exhibited a very beautiful negative of the Pleiades and other stars, obtained by Mr. Rutherford. Some interesting details of the star photographs of Mr. Rutherford will be found in Dr. Vogel's recent articles in our pages on astronomical photography in America.

After some votes of thanks the proceedings terminated.

Talk in the Studio.

ANOTHER USE FOR PHOTOGRAPHS.—During a recent parliamentary debate on the Women's Disabilities Bill, Mr. Scourfield, in opposing it, expressed his disbelief in the genuineness of petitions sent to the House, professed to be signed by women desirous of votes. "As a means of testing whether the women of England really wished for the power of voting, he would suggest—and commend the suggestion to the attention of the Chancellor of the Exchequer—that every person signing a petition in favour of the extension of the franchise to women should be instructed to accompany the signature with a photographic portrait, and that Mr. Darwin or Professor Owen, who could distinguish the sex of animals from very trifling signs, should be retained to decide from an examination of the pictures as to the sex of the person represented, for he could not help suspecting that many of the signatories were not women, but men in women's clothing (laughter)."

ENLARGED AND REPRODUCED NEGATIVES.—We have just been favoured by Mr. J. W. Pickering with three very perfect photographs, which very excellently illustrate the value of his method of reproducing and enlarging negatives, described in our last YEAR BOOK. The subject is an alto-relievo of the Ascension of Christ, and is admirably photographed; the original being 6 inches square, another is 10 inches by 10 inches, and another 12 by 12 inches; and it is absolutely impossible to detect a trace of deterioration or lack of excellence of any kind in either of the enlarged reproductions.

To Correspondents.

A CONSTANT SUBSCRIBER.—The size of the mount for the Victoria card is 5 inches by 3½ inches. The size of the print is 4½ by 3 inches, and that is, of course, the size of the cutting-glass. The margin round the print is one-eighth of an inch sides and top, and three-eighths of an inch at the bottom. A saturated solution of sulphate of iron will produce crystals if a portion of the water is evaporated, or if the weather becomes cold, as the solvent power of the water is less at a low temperature than at a high temperature. The presence of a few crystals at the bottom of the bottle is satisfactory, as indicating that the solution is saturated. The addition of a little more water will readily dissolve the crystals.

1871.—Use a collodion with good body, containing very little bromide, and sufficiently long kept to acquire the colour of pale sherry; develop with a 10-grain iron solution containing a little gelatine; and intensify with pyrogallie acid and silver. If, after fixation, you require greater density, apply a 10-grain solution of bichloride of mercury, wash, and apply a 1-grain solution of iodide of potassium. You will generally acquire intensity enough by these means to give a vivid black-and-white print. Should you desire still further density, you may use pyro and silver again, after the iodide solution. 2. Only resort to boiling down a bath after neutralizing and sunning have failed.

ALF.—An acetate bath should always be mixed a day or two before it is used. If used at once it is not only apt to bleach, but also to produce a factitious appearance of toning, which disappears when the print is immersed in the fixing bath.

W. FAUSSETT.—Your gold toning bath made with vinegar instead of water cannot be used with advantage. The best plan will be to add protosulphate of iron to reduce the gold, wash the black precipitate of gold which will be thrown down, and then reconvert it into chloride by means of nitro-hydrochloric acid.

A. REEVES, referring to the claim of Mr. Jeffryes in relation to "seroll portraits," admits his priority of suggestion, but thinks that the crude suggestion does not constitute "working out an idea." As both gentlemen have contributed their quota to the method, any relative disparagement of each other's efforts is not desirable.

R. M. D.—The exposure for a collodion positive need not be so long as for a negative, but the chief difference is in the mode of development. For the positive it is desirable to add a little uric acid as well as acetic acid. A solution containing

Protosulphate of iron	15 grains
Acetic acid	15 minims
Nitric acid	1 minim

to an ounce of water will answer well. The development must not be continued nearly so long as for a negative, but stopped, and the solution washed away the moment the details have become visible. Fixing with cyanide is preferable to fixing with hyposulphite. We prefer dark velvet for the backing; black varnish gives a less pleasing effect. Crystal varnish, made by dissolving gnu dammar in benzole, answers well for varnishing positives.

C. E. F.—We are quite familiar with the difficulty you describe, but the steps you have taken to surmount it are precisely the opposite to those required. Instead of reducing the activity of your developer, you need to increase it. With an active developer reduction commences at the moment of contact; with a developer containing excess of restrainer the development does not commence rapidly. The sweep of the solution on the plate drives away a portion of the free nitrate before development commences, and so leaves the place upon which the solution was poured thinner, having been robbed of a portion of its free silver. Certain kinds of collodion are more liable to this defect than others, but by the use of a newly mixed developer of 15 grains of protosulphate and 15 minims of acetic acid to an ounce of water, and care in throwing the solution over the plate gently, these stains may generally be avoided. If you use a flat glass dish for development, like that recently described by Mr. England, you at once escape all difficulty. A vertical bath may be used, but the flat dish is better, and admits of the use of a small proportion of solution fresh for each plate.

T. B. HUTTON.—We are glad that you find the ridge-roof studio, built and arranged as we have so often recommended, so successful. The examples of portraiture enclosed are very good. The question how far good photographs need retouching, or how far they may be improved by retouching, is a wide one. As a rule, a little skilful retouching by a capable artist will render a photograph more pleasing without being less truthful. It may not need retouching, but it may be improved by it. Bad and unskilful retouching, and all excess of retouching, which works out all traces of life and nature, a kind of retouching which is only too prevalent, is much to be deprecated, as destroying all the truth of photography, and not substituting the truth of art.

Several communications in type are compelled to stand over.

Several Correspondents in our next.

COPYRIGHT IN PORTRAITS.

NORWITHSTANDING that much has been written on the subject of copyright in photographic portraiture, and that the question has been repeatedly raised in courts of law, considerable misapprehension and uncertainty seem to prevail as to the actual law on the subject. We are by no means sure that we can determine the question in all its bearings with anything like absolute certainty, as the wording of the statute is undoubtedly sufficiently clumsy and ambiguous to admit of differences of opinion as to its meaning. On one or two points of importance to photographic portraitists it is, in our estimation, however, tolerably clear, notwithstanding the misconceptions which prevail. We shall very briefly state our view of the matter.

The misapprehensions to which we allude are various. The first we shall mention is a singular one. A correspondent sends us a letter he has received, and asks our opinion as to the dictum it contains. It runs as follows:—

“2nd May, 1871.

“DEAR SIR,—In reply to your letter of 29th ult., I maintain that, by the universal custom of the trade of photography, the person photographed has no special property in the negative, which undoubtedly belongs to the photographer; consequently he is justified in supplying from such negative any number of photographs to any number of disinterested parties.”

It is scarcely necessary to affirm, we imagine, that the conclusion here expressed is utterly erroneous. That the negative is the property of the photographer we unhesitatingly maintain; but that he is therefore at liberty to supply prints to other persons than the sitter without the consent of the sitter is manifestly opposed at once to equity and common sense. It is not necessary to point out the inconveniences which might arise from such a course; nor can we define the exact legal risks involved; but it is probable there is more than one remedy for the sitter in case the photographer sells his portrait without his permission. In our view, no copyright is obtained by either photographer or sitter in the ordinary transaction of the business of a photographic portraitist. A copyright in a photographic portrait can only be acquired under special circumstances not generally existing, but to which we shall refer presently. The sitter has, it has been alleged, a property at common law in his own face, and, we presume, in the design thereof; in which case he could maintain an action against the photographer for disposing of copies of that face without his permission. The photographer is, moreover, entrusted with a photographic copy, in the form of the negative, of the sitter's semblance, for a special purpose, and any use of that negative for other purposes would constitute a breach of trust for which the photographer could be rendered amenable.

But there are circumstances under which a copyright in

a photographic portrait can be acquired. The copyright in a photographic portrait commissioned in the ordinary manner can be acquired by either photographer or sitter by the simple process of an agreement or assignment in writing. Without such written agreement we hold that no copyright is acquired by either party in the photographic portrait as usually commissioned. The first section of the Act reads as follows:—

The author, being a British subject, or resident within the dominions of the Crown, of every original painting, drawing, and photograph which shall be or shall have been made either in the British dominions or elsewhere, and which shall not have been sold or disposed of before the commencement of this act, and his assigns, shall have the sole and exclusive right of copying, engraving, reproducing, and multiplying such painting or drawing, and the design thereof, or such photograph, and the negative thereof, by any means, and of any size, for the term of the natural life of such author, and seven years after his death, provided that when any painting or drawing, or the negative of any photograph, shall, for the first time after the passing of this act, be sold or disposed of, or shall be made or executed for or on behalf of any other person for a good or valuable consideration, the person so selling or disposing of or making or executing the same shall not retain the copyright thereof, unless it be expressly reserved to him by agreement in writing, signed at or before the time of such sale or disposition, by the vendee or assignee of such painting or drawing, or of such negative of a photograph, or by the person for or on whose behalf the same shall be so made or executed, *but the copyright shall belong to the vendee or assignee of such painting or drawing, or of such negative of a photograph, or to the person for or on whose behalf the same shall have been made or executed*; nor shall the vendee or assignee thereof be entitled to any such copyright unless, at or before the time of such sale or disposition, an agreement in writing, signed by the person so selling or disposing of the same, or by his agent duly authorized, shall have been made to that effect.

It has been maintained by some that the sentence which we have placed in italics gives the copyright to the vendee, or to the person on whose behalf the portrait is executed, without any written assignment, and, hence, that the copyright rests in the sitter; but it seems to us that this is negatived by the closing sentences of the section, which state that the vendee shall not be entitled to the copyright except by an agreement in writing. But even if this were not so, it is clear that in any case the sitter would not be entitled to the copyright, unless he purchased the negative as provided for by the terms of the statute. And further, to secure the copyright to the sitter, even if he were entitled to it, he must comply with the registration conditions, which not one sitter in ten thousand would dream of. Under the ordinary circumstances of photographic portraiture without written agreement or registration, we maintain, then, that no copyright exists.

But there are circumstances in which a copyright is obtained by the photographer without any agreement or assignment whatever. The author of any original painting, drawing, or photograph, produced, not as a commission, but by his own choice, acquires an exclusive property or

copyright of the design therein, and he retains this until he for the first time sells it, and in the case of the photograph, he retains it until he for the first time sells the negative, as the statute expressly provides. This being so, we are distinctly at issue with the views maintained by Mr. Cunningham in a letter on another page. He affirms that in a recent case of alleged piracy, Mr. Taunt, the photographer, had no copyright in his photograph of the Oxford boat crew, because no written agreement between himself and the crew had been entered into. But if the crew, as was doubtless the case, sat to Mr. Taunt at his request, then assignment or agreement in writing was in no sense necessary, any more than would be the agreement of the artist's model sitting for a painting. The photograph was not commissioned by the crew, but produced by the photographer for his own purposes, and the copyright rests in him until he disposes of the negative. The observation of Mr. Lewis was, therefore, no *non sequitur*, but a bare statement of the fact. The case of Col. Burke has no bearing on that of Mr. Taunt, as he did not sit to the photographer for the photographer's own purposes. Neither would the Oxford crew, or any of them, have any right, we apprehend, as Mr. Cunningham suggests, to prevent the farther publication of the group. The supposed case of Mr. Cunningham would not apply. If Mr. Cyanide, being commissioned to take the portrait of Mr. Blank, produced, besides the commissioned portrait, another negative to use for his own purposes, he would subject himself to legal action, the form of which, as a layman, we need not discuss. Such conduct would, moreover, be a manifest breach of trust, which, independently of its legal risks, would so thoroughly ruin the reputation and connection of any portraitist, that it is scarcely a contingency sufficiently probable to consider.

The notion that a celebrated person sitting to a photographer constitutes a valuable consideration in the sense held by Mr. Commissioner Kerr, and argued by Mr. Merriman, appears to us to be the sheerest nonsense. The consideration as mentioned in the Act is the equivalent of payment. The question at once arises, therefore, payment for what? If there be no commission or purchase, there can be no payment. If the royal duke, or Mr. Bright, or boat-crew, sit to the photographer at the request of the photographer, and for his purposes, there is nothing for any of them to pay for, and therefore their sitting cannot be regarded as the substitute or equivalent for any payment. If the royal duke, or M.P., or boat-crew applied to the photographer for a number of portraits, and offered as payment to sit, and to enter into an agreement assigning the copyright of such portraits, then the sitting might be regarded as part of the valuable consideration mentioned by the statute; but where the sitting is made at the request of the photographer, and for his own purposes, it is clear that the notion of treating the sitting as a consideration is, *pace* Mr. Commissioner Kerr and Mr. Merriman, utterly absurd.

The motives of the Oxford crew or of other distinguished persons in sitting at the request of photographers for portraits for publication scarcely affect the question in any way, legally or morally. If the photographer attain his copyright in accordance with the provisions of the statute, the intentions of the sitter as to the steps the photographer shall be at liberty to take in vindicating his copyright do not affect the question. Nor if the conditions of the statute are not complied with, will good-will on the part of sitter make the copyright valid. But if the sitter possessed the power, which Mr. Cunningham suggests that eminent persons fancy they have, of ordering the sale of a portrait to cease at any time they think fit, they might do the photographer serious injustice, and cause him serious loss. The contingencies, however, to which sitters, photographers, or pirates are subject, only affect the question so far as they communicate additional importance to a clear understanding of the matter. If photographers in the position of Mr. Taunt have a copyright without written agreement with any one in photographs which they produce uncommissioned, solely

for their own purposes, the consequences of infringing such copyright, as must the consequences of all law breaking, rest on the heads of the law breakers, and it is cruel kindness to attempt to make the pirates believe that they are the victims of the capricious decisions of incompetent magistrates. In the case of Mr. Knight, it appears that he voluntarily run the risk of breaking the law by selling a print about the copyright of which he was uncertain, the only information on the subject being derived from a boy twelve years of age, whose parents had been convicted of piracy. Mr. Cunningham sympathises with the pirates because he believes the law is strained to oppose them. We sympathise with them so far as they are poor, ignorant, and sorely tempted, but not where, without the excuse of ignorance and poverty, they voluntarily run risk of breaking the law and defrauding the honest trader.

A NOVEL NITRATE BATH.

A NEGATIVE nitrate bath of a very novel and curious character is described in the letter of our esteemed American correspondent. Mr. Black, of Boston, has forwarded to him a large negative, the plate for which was excited in a nitrate bath containing only fifteen grains of nitrate of silver to each ounce of water. This is, of course, an unusually weak solution for a negative bath, but the especial novelty does not consist in this fact. The negative bath is, as our readers know, rarely employed of a strength less than thirty grains to the ounce; but we have known cases in which an old bath which has been kept in successful working for some time has been found, on careful testing, to have been reduced to a strength of eight grains. But the startling peculiarity of Mr. Black's bath consisted in the fact that it contained not less than fifteen ounces of nitric acid in five gallons of nitrate of silver solution, or about half as much nitric acid as nitrate of silver. Col. Stuart Wortley described a bath for producing instantaneous pictures in which he employed two drops of nitric acid to each ounce of silver solution; but Mr. Black's bath contains more than four times that proportion. In the old days of collodion positives, we remember a bath being recommended for use with a highly bromized collodion containing four minims of nitric acid to the ounce of solution. In using more than double that proportion Mr. Black discards bromides, and uses a chloride in the collodion, in what proportion, or in what relation to iodide, is not stated. The claims made for this new formula are, that it gives equally good or better results, and works more quickly than the usual method with a forty-grain bath without excess of acid, and the deposit of silver, contrary to what might have been anticipated, is stated to be finer than that obtained in the ordinary manner. Mr. Black is an exceedingly skilful and thoroughly experienced photographer, whose dictum is of value in relation to any novelty he may recommend. We shall look with interest for further development of this novel style of working.

OBITUARY.—SIR JOHN F. W. HERSCHEL, BART.

THE death of Sir John Herschel removes one of the group of philosophers to whom photography owes its birth. Contemporaneously with Daguerre and Talbot he was experimenting in the production of sun-pictures, and was the undoubted discoverer of the use of hyposulphite of soda as a fixing agent. In January, 1839, before the publication of the experiments of either Daguerre or Talbot, Sir John Herschel produced a camera image of his telescope on paper prepared with carbonate of silver, and fixed with hyposulphite of soda. "This," Sir John observes, in a letter addressed to us, "was, I believe, the first picture ever fixed from an optical image ever taken in this country; at least, I have heard of none earlier." His first experiments with the hyposulphites as solvents of the salts of silver were published

in the *Edinburgh Philosophical Journal* in January, 1819. Throughout the whole of his long scientific career Sir John Herschel has devoted himself ardently to every form of research connected with the physical laws upon the operation of which photography is based; and besides valuable theoretical contributions on the science of light, he has added to photography many practical processes. Various of these (classed, at the time of their discovery, under various heads, amongst which we may name the cyanotype, the chrysotype, the amphitype, and other processes), although not now applied in their original form, have furnished the bases of operations in general use. In his early experiments he discovered that the range of substances sensitive to the action of the sun's rays was much more extensive than had been imagined, and expressed a conviction that the idea associated with photography consisted no longer in "an insulated and anomalous affection of certain salts of silver or gold, but one which, doubtless, in a greater or less degree, pervades all nature." To mention the specific facts of photography associated with the labours of Sir John Herschel would involve the writing of a full memoir of his life; we may mention, however, that to him was due the discovery of the extreme heating and actinic rays of the spectrum beyond the red and the violet; to him was due the first use of glass plates in photography; and the varied range of iron processes. He experimented largely in the production of photographic images in natural colours, and with some success. One of his latest contributions to photographic literature was a communication which he addressed to this journal upon this subject, in which, without expressing a disbelief in its possibility as a fact of any practical value, he furnishes an illustration of his idea of its difficulty. He remarks:—

"The problem of chromo-photography here presented may be likened to that offered to the decipherer who should be called on to discover the purport of a succession of letters which, interpreted by their proper key, should land him, not in an intelligible grammatically constructed and orthographically spelt English document, but in the same document concealed in another cipher equally or more difficult, and requiring to be read by its own proper key, which need not of necessity be that of the first cipher." Accompanying this communication Sir John forwarded a cryptographic puzzle to test the ingenuity of our readers.

Few men have occupied a higher position as a scientific philosopher than Sir John Herschel. At once an original investigator in a large range of physical sciences, and an expounder luminous and popular, but never superficial, his impress upon his age will never be effaced, nor his place readily filled. Probably no man has contributed so largely to the science of photography as he, his interest continuing from the earliest days of the art to the last days of the philosopher. He died, full of years and full of honours, on the 11th instant, aged seventy-nine years.

AMERICAN CORRESPONDENCE.

OUR EXHIBITION—CONCERNING HYDRATE OF CHLORAL—NITRIC ACID INSTEAD OF NITRATE OF SILVER.

Our Exhibition, to be held in this city in June, is now absorbing more attention than anything else, and great preparations are being made to have a most interesting and profitable time. In addition to the exhibition of photographs, chemicals, and apparatus, which we expect will crowd one of the largest halls in the country, and where we hope to see England well represented, there will be two of Prof. Morton's inimitable lectures on light; a grand lantern entertainment, which will bring into use a variety of lights adapted to the purpose. The meetings of the Association, aside from business matters, will be devoted mainly to the reading of scientific papers from those eminent in the art, and to discussions on practical topics; the Committee on the Progress of Photography will make an interesting report; and the Committee on the Scovill and Holmes Medals

will also have many interesting things to report. Among the matters already offered to the committee in competition for the medals is a process for burning-in on glass; another for producing "imperishable" photographs on porcelain; others for retouching varnishes, plate-holders, backgrounds, &c.; all of which are to be examined for their value as improvements in the art of photography. The whole will open with a grand public reception; and to all we invite our *conferes* from abroad, promising to take special care of them if they will but come. We are confidently expecting our good friend the Editor of the News as our guest.

Concerning Hydrate of Chloral.—You have already suggested the use of this compound in collodion to your readers. With us we find it most effective in ferrotype collodion, as it seems to impart an extra brilliancy to ferrotype pictures. Mr. David Duncan writes me concerning it as follows:—

"Recent experiments with hydrate of chloral in collodion, as suggested in the *Philadelphian Photographer* a short time since, have been so far satisfactory. Dissolving about one per cent., as recommended in collodion, certainly increased the sensitiveness, although not to an extraordinary degree. A cadmium collodion, which gave pictures slightly veiled, yielded clear negatives when the chloral was added, without loss of sensitiveness. It dissolves readily, and does not leave cloud or sediment. It imparts also an extra brilliancy to ferrotypes, and does not, apparently, affect the bath.

"The hydrate of chloral is now extensively used in medicine, both in Europe and this country; and although discovered thirty years since by the famous German chemist Liebig, it has attracted the attention of chemists, medical men, &c., but a very short time, being brought before the Medical Society of Berlin for the first time June 2nd, 1869. It results from the action of chlorine on alcohol, the latter of which gives up five of its six equivalents of hydrogen to the former, producing five equivalents of muriatic acid, and combines, in their place, with three equivalents of the chlorine to form the substance we write of. The change is supposed to take place in the following manner:—The alcohol ($C_2H_6O_2$), by the loss of two equivalents of hydrogen, becomes aldehyde ($C_2H_4O_2$), of which the radical acetyl (C_2H_3) gives up its three equivalents of hydrogen, and takes three equivalents of chlorine, forming a new radical (C_2Cl_3), and this, combining with one equivalent of the oxygen, and with the remaining equivalent, each of hydrogen and oxygen, form chloral ($C_2Cl_3O \times HO$), or a variety of aldehyde, in which the three equivalents of hydrogen of the radical are replaced by three equivalents of chlorine.

"Anhydrous chloral is an oily, pungent fluid. On standing it undergoes decomposition, and ultimately becomes solid. It combines with water to form the crystalline hydrate, therefore, as pure chloral readily undergoes decomposition, the comparatively stable hydrate is the form in which it is best kept for use. It is used in medicine because it is an excellent anodyne and soporific, equal, in these respects, to chloroform, without the unpleasant and often inconvenient local irritation produced by that remedy. For giving a nervous and excited photographer a good night's rest after a hard day's work it is invaluable. The dose is from thirty to fifty grains."

Nitric Acid instead of Nitrate of Silver.—Here is a photographic nut for you to crack. It has just come to my hands, and I have not had the time to try it yet. It comes from one of our oldest and best photographers, and is, therefore, worthy of trial. I allude to Mr. J. W. Black, of Boston, who says:—

"I send you a 11 by 14 negative, made to-day, taken under a not very favourable light, in a silver bath containing only 15 grains of silver to the ounce of water, with 15 ounces of C. P. nitric acid to five gallons of solution. The bath has been in use one week. I use no bromine, but chlorine instead in my collodion; found it to make as good a negative as with the usual amount of silver of 40 grains to the ounce, and worked very much quicker."

Mr. Black says that it makes a finer deposit of silver, works smoother and softer, and is more economical; he did not see the use of so much silver in a bath when so little was used. A few years ago 80 and 90 grains of silver were used in printing, now hardly any one uses over 40 grains. There is no danger of getting heavier shadows without bromine in collodion if the proper exposure is given.

I submit this to you, and shall send you some of the results presently.—Very truly yours,
Philadelphia, May 1st, 1871. EDWARD L. WILSON.

ENLARGED LANDSCAPES.

BY H. BADEN PRITCHARD.

I CANNOT help thinking that the subject of large photographs, to which Mr. Dunmore called attention on a recent occasion, is one which, sooner or later, will attain to very great importance. It seems to me such a pity that the grand scenery of Switzerland and the Tyrol, which is so frequently reproduced in stereoscopic and cabinet pictures, should not be rendered in a size and form more suited to the subject, so that we might be in a position to form a fairer and more true conception of the original landscape. The tiny sketches of this kind now taken are all very well for the album and the stereoscope; but the question arises, whether we cannot obtain pictures of larger dimensions, such as would be suitable for the library or dining room, and would take the place of engravings that now usually occupy our walls? Anyone who has viewed one and the same photograph in its original size, and then enlarged upon a screen by the solar camera or lime-light apparatus, cannot have failed to perceive the very marked difference exhibited by such pictures; the impression upon the mind of the spectator being much grander in the case of the enlargement.

Of course, there are many difficulties to be urged against the production of these monster prints, but these are, I think, for the most part to be avoided. A special apparatus for enlarging is required, as also a special operator well versed in his work, for it is not to be supposed that in this branch of photography, as in many others that are being developed from day to day, that the ordinary manipulator can undertake delicate manipulations of this kind without the possession of certain appliances and some amount of skill. Indeed, to produce successful enlargements of this kind it would, no doubt, be necessary, supposing they were obtained by direct enlargement in a solar camera—the method, beyond doubt, best suited to the purpose—to give one's whole attention to the subject, and to study it as a distinct branch of the art.

By making a special business of this class of photography, experience and skill would soon be gained, and more perfect pictures obtained than it would be possible for an ordinary professional photographer, engaged in miscellaneous work, to produce. It is, in truth, a common error with photographers of the present day to attempt too much. Our art is getting so extended, its applications and modifications are so numerous, that it is simply impossible for any one man to keep himself *au fait* with every method or process that is made known; if he desires success, he must confine himself to one particular branch, and pursue it alone and uninterruptedly, otherwise he will be powerless to reach such pioneers as may have already made way along that particular route before him.

But there is something else to be mentioned in regard to pictures of this kind. With the general public it has always been considered a *sine qua non* that all photographs should be perfectly sharp and distinct, and that, indeed, they are best seen through a powerful magnifier. Now, so long as this idea prevails, it will be impossible almost to render enlargements popular, as they will always fail to satisfy the vulgar test usually applied. Once, however, get the public to look upon these large views in the same

way as they would paintings and engravings of like size—viz., at a distance whence a comprehensive view may be obtained—and there is no further doubt of their ultimate success as a commercial speculation. Who would not, for instance, purchase enlarged photographs of some of England's and Gordon's charming landscapes, were such works of art obtainable printed in permanent pigments, and sold, perhaps, for half the price of an engraving of similar size? The gems of lake and mountain scenery produced by Constant-Delessert are, again, eminently suited for amplification, as, indeed, are all those pictures of exquisite delicacy which have received little or no intensification.

As already stated, it is by no means every photographer who can manage these enlargements. If produced by means of the solar camera, some very expensive apparatus and considerable experience are necessary. But these points should not be considered as serious obstacles in the matter, seeing that an important branch like this should furnish work more than enough for any photographers devoted exclusively to this class of labour. Portrait enlargements have never been much favoured by the public, and the reason of this is obvious: the amplifications were often as large as—nay, even larger than—the original models, and, besides occasional distortion, the numerous little defects interfered materially with the complexion and features, which invariably required retouching before being presentable. With landscapes, however, when enlarged even to the most colossal dimensions, no chance of distortion need be feared; but, on the contrary, small details are thus thrown up and developed, which previously were totally hidden from view. No better proof of this can be given than that afforded by good enlargements in a dissolving views apparatus, when the appearance exhibited is one very closely allied to nature itself.

THE PROPOSED TAX ON PHOTOGRAPHS CONSIDERED.

BY W. T. BOVEY.

STUDENTS of modern chemistry are often wont to smile over the absurd infatuation which induced the alchemists of old to waste a life of laborious research in vain attempts to transmute the baser metals into precious gold. It must, however, be admitted, as evidence in favour of those ancient fosterers of chemical science, that their governing ideas were at least consistent, inasmuch that they sought means to convert matter of a grosser kind into a substance possessive of enhanced purity and value. They certainly made no attempt to produce something out of nothing. Giants of intellectual perseverance, they worked by the light of their day and generation, which certainly did not include the advantages of gas, paraffine, electricity, and lucifer matches. We, possessing all these, may work in a blaze of light, so we put on a great show of superior wisdom, and egotistically pool-pool the folly of our erring ancestors. Yet, if truth must be told, we are bound to confess that, like the portly simpletons of "Gotham," we are wont sometimes to perform very foolish parts in the drama of life, not the least of which is the new-fangled notion, now growing into fashion, that conceives of the possibility of extracting something out of nothing.

Bombastic and empty-headed communists, and other remodelers of society of like kidney, are seeking to elevate labour by knocking away the natural props on which all useful labour depends for its protection, procreation, and existence. Frantically those purveyors of logicless rhetoric shout "liberty," whilst they crush poor liberty beneath their iron rule. Loudly they boast of equality, whilst they are blind to the fact that equality implies a cessation of labour, for labour made aristocratic cannot stoop to "vile work," and a community subsisting on non-reproductive means must soon sink into a state of bankruptcy; and which, unchecked, would drive men back to a savage state of existence, and an internal disorder. *Wealth cannot be created out of*

nothing. Happily, the ridiculous doctrines taught by communists can never take deep root on English soil. Your true Briton loves work, or, at least, he boasts of such a liking. Rest the matter as it may, he goes on working, and only kicks against fate when poverty or the tax-gatherer crosses his path to disturb the even tenor of his way. Yet both are natural accompanists of civilization, and whilst poverty will ever exist, the periodical budgets of Chancellors of Exchequer will be equally lasting. What a boon would it prove to national purse-bearers if they only knew how to provide the something needed to grease the wheels of State out of nothing! "Take nought from nought, remains nought;" at least, a man of figures reaches this finding in the arithmetical problem, and, as a rule, Chancellors of Exchequer are pretty apt in the vulgar rules taught them in days of boyhood, which rules, in the main, are generally found correct. But, although the impossibility of extracting something from nothing can be comprehended by any one of sound intellect, the possibility of drawing a great deal from a very little requires a higher range of mental power to readily understand; most certainly, none but a born genius could hit upon the plan.

All hail! that genius lives, moves, and has a being. We "Britishers" obtain his ideas from over the water. Our Chancellor has received the earliest intimation of the discovery of a salve that, "well rubbed in," would heal the sore places in his budget. "Tax vanity," prescribes the genus. Now, vanity being vaporous—a mere nothing—our Chancellor cannot, of course, see his way clear to make good his defeat by levying a tax on nothing. Our genius is, however, equal to the occasion. "Photographs are offsprings of vanity; tax them" Behold the simplicity, the wondrous equality, of the arrangement! The larger the amount of vanity, the more frequent will it sit before the camera; thus vanity will be taxed in just proportion with its degree. Besides, "the negatives cost little or nothing," and the prints are produced at about the same outlay of cash. A deal of money was presented to the lucky individual who suggested the perforation of postage stamps, and it is scarcely probable that his saviour of our national solvency can fail to meet with his reward. Mr. Lowe, in duty bound, should at once snap his fingers in the face of opposition. Stay; he has recently burnt his fingers whilst playing with lucifer matches; let us hope that he will be restored to his normal coolness; that he may be able to reflect ere he is tempted to act on the arch-tempter's proposal. And how tempting the conditions! "Photographs cost little or nothing for their production." I am inclined to think that the astute Chancellor is too well versed in the intricacies of political economy to catch at the bait so enticingly presented. That wily gentleman is well aware that there are many things besides photographs which might be taxed on similar grounds. He is fully aware of the fact that nature offers the whole of her mineral wealth and vegetable production in exchange for labour, and that the value of an object is simply the value of the labour expended in its production. Articles which require but little skill to produce always command a supply of labour in excess of the demand, therefore such objects are sold cheap. Under circumstances where exceptional skill that requires long training is needed, the articles produced will ever command high prices, because exceptionally high skill is rarely injured by competition. There are, of course, instances of sudden riches being obtained by lucky findings of gold or precious stones, but if we take the losses of the unlucky searchers into consideration, the fortunate one has scarcely found that which, if divided, would remunerate the whole of his fellow seekers. Nature is wonderfully harmonious in her dealings, depend upon it.

Now, taking it for granted that the materials of which a photograph is composed cost little or nothing, it would prove no difficult task to pile up necessary and contingent costs which would suffice to show that a photograph is not produced at so cheap a rate as is generally supposed.

1st. There are the time and labour expended on the production. Both are of money value.

2nd. There are the building, the cameras, lenses, accessories, &c. These cost a considerable sum, the outlay for which the photographer has an undoubted right to recover by dividing the amount among the number of pictures he sells.

3rd. There is waste of chemicals, occasioned by re-sittings; repairs and depreciation of working plant; wages to pay; bad debts to allow for; printing and stationery to be provided; in short, if we go into all the details of expenditure, we might readily expect to convince the most sceptical that a photograph, after all which has been said to the contrary, does cost something more than "next to nothing," for, in its production, a vast amount of diversified labour has been expended.

Apart, however, from the question of cost of production I ask, Would it be politic to tax photographs? I reply emphatically, it would not. A tax, to be kindly received and tolerated, must be concealed, as far as possible, from the public gaze. Simultaneously, or in turn, we have had taxes levied on our teas, sugars, coffee, bread, wines, beer, and spirits. And that famous taxing-master Pitt, after levying duties on window glass and daylight, he, "Lulu" fashion, took a tremendous leap, and alighted in the salt-box. But in most of the articles taxed, the duty is paid into the State coffers before the goods reach the retail dealers; and custom has made the imposts sit tolerably easy because they remain in the background. Our clever Chancellor of the Exchequer must be strangely ignorant of English prejudices, or he would never have made shipwreck of his Budget. A more fatal error he never committed than when he proposed a tax on matches; and equally fatal would the taxing of photographs prove, if photographers for the once will unite, and, by cohesive effort, show a bold front should the tax-collector be set on their track. If photographs are to be taxed, enlist the sympathies of the public by giving them to understand that the extra burden must be cast on their shoulders. Make them aware that, for the sweet-sounding "*Ex luce, lucellum*," an extra halfpenny must be charged for each copy of the motto. Such an impost would be hated by the "vain" public; and, to stare the broad truth in the face, those who watch the signs of coming events see that society grows democratic in its notions. It will pay taxes readily, but they must not be too obtrusively paraded.

If, in the future, it is seriously intended to tax photographs, I would strongly urge on Mr. Lowe, or any finance minister who may adopt the scheme, to levy the duty on the raw material, for a tax on the finished photograph would be both impolitic and intolerable. Speaking personally, I regard indirect taxation in any form to be a great mistake. It might work smoothly because it has been engrafted in our institutions by custom, but it would be by no means difficult to show that consumption is lessened and labour curtailed by its operation. Besides, it presses unequally on individuals; the family man is taxed for the non-producing children who are destined to maintain the State hereafter; the miser enjoys immunity from taxation because of his niggard abstemiousness, and so on. But I am drifting into the depths of economical science, so must bring up short to offer, by way of conclusion, a word of instruction and advice.

Photographers! at the first hint of coming danger, rally around one common standard, appoint a committee to organise opposition, and the lever of opposition, if judiciously handled, will, as a matter of course, succeed. If the small cost of a photograph is urged against you as an excuse for taxation, point to the canvas, paint, and brushes of the painter artist. I have just been told of a picture now hanging at the Royal Academy which realised £8,000, and took eight months to paint. Why not tax such pictures as that? The material surely cost proportionately less than the material of which a photograph is composed! We are

told that *art* must remain untrammelled—free. Well, we have certainly a dearth of art culture in England; but if Mr. Lowe will only read the excellent article on the subject by Tom Taylor, he will perceive that photography is our sheet anchor, for by its aid *fac similes* of the most famous works of art are being cheapened, and made accessible to the million. There has hitherto existed a deplorable lack of taste among English artisans, simply because art products have been kept beyond the reach of their slender means. A love of that which is beautiful is as inherent in an Englishman as in an equally taught foreigner. But our continental friends of Germany and France enjoy superior advantages. It was but a few years ago that the walls of every English cottage home were disfigured with glaring daubs made still more hideous by dottings of gold and silver. The workman was regarded as a mere child, and amused accordingly. Photography has done much to revolutionise all that nonsense. Keep the tax-gatherer from the art, and it will in time do for the English labourer what it has already accomplished for the more fortunate German. As labour is wealth, a nation's interest is best studied by improving the capabilities of the producers. A tax on the means of conveying knowledge means the intellectual impoverishment of the poorer members of a community, and that kind of impoverishment denotes a growth of moral degradation. The human mind must have something to feed on—wheat or tares. The duty was removed from paper. Oh, how glorious the fruits of the withdrawal! Books cheapened; newspapers multiplied by tens of thousands; and who can calculate the results? I cannot, for the fruits of knowledge are boundless.

ON FIXING AND INTENSIFYING COLLODION NEGATIVES BY DAYLIGHT.

BY HERMANN KRONE.*

To obtain soft negatives with delicate half-tones, it is usual, as we know, not to develop the plates too deeply, but, if necessary, to intensify after fixing. Those who are in the habit of fixing with hyposulphite of soda require to exercise extra care in the washing of the plate, and cannot even then prevent the presence of a small quantity of this salt, which, by reason of the capillary action in the pores of the image, remains in the film. On this account it may be asserted that the more carefully and thoroughly a hyposulphite negative is washed the more durable will it be. Granted that careless washing influences, in any case, the permanence of a negative, there is yet one other circumstance which exercises an essential action upon the stability of the plate, one to which, as yet, no attention has been paid. There is a great difference, namely, in the durability of a plate, whether the same has been fixed in hyposulphite in the presence of daylight, or in obscurity, or whether it has been intensified after being fixed.

1. Those negatives which are fixed in the presence of daylight are, by its means, modified as regards their future behaviour, although there is nothing dissimilar at first sight in their appearance between such negatives and those fixed in darkness. When imperfectly washed, however, they gradually become covered with yellow stains or spots, while those badly fixed in darkness show white patches, increasing in size, but with no yellow crystallization.

2. Negatives fixed with hyposulphite in darkness, well washed, and then, in the presence of daylight, intensified with pyrogallie acid and silver, soon become covered with yellow spots when exposed to the sun in the printing frame, assuming at last a yellow tint all over; the more hyposulphite there remains in the pores of the film, and the longer the intensifying liquid has remained upon the negative in daylight, the more yellow, indeed, will the plate become; while other negatives, fixed and washed in exactly the same manner, but intensified in darkness, will be found to remain for years perfectly clear and free from colour,

* Licht.

notwithstanding their frequent employment in the frames.

3. If a negative is fixed with hyposulphite of soda, and well washed in the dark, then inspected by daylight, and again taken into the dark room to be intensified with pyrogallie acid and silver, there will be found to be no modification of the film take place hereafter, either in the transparency of the plate, or the colour thereof, despite its exposure to sunshine in the printing frame for lengthened periods.

By a close investigation of these circumstances, we shall find that, as regards the third instance just enumerated, the residual soda retained by the capillary action of the film has not suffered any modification by the action of daylight any more than the whole surface of the image. In the first case, however, a change takes place in the hyposulphite of soda solution which is impregnated with silver salts, as likewise in instance No. 2, where the modification is brought about by the aid of the silver in the intensifying liquid with which the residual soda is treated. In both these cases the hyposulphurous soda and silver is modified in such a manner that it is with difficulty dissolved in water, and is less capable of removal, therefore; more residual soda thus remains behind, and by the repeated action of light, or more rapidly even by exposure to a moist atmosphere, this gives rise to the formation of sulphide of silver, which at first is seen in the form of yellow spots, but which subsequently colours the whole surface of the plate.

The best remedy for No. 1 instance seems to be repeated subsequent treatment with fresh and strong hyposulphite solution, which appears to dissolve away the double salt; in the second case there would appear to exist no specific whatever, as the formation of sulphide of silver already commences during the operation of intensifying in the presence of daylight.

This circumstance reminds one of the analogous behaviour observed by Stas of sulphurous acid, which, when prepared in the dark, and added to a solution of silver, forms sulphite of silver, which remains unchanged for a notable period; under the influence of daylight, however, a modification sets in, and sulphide of silver is formed upon the addition of a silver solution.

ON THE PREPARATION OF MEDALS BY MEANS OF PHOTOGRAPHY.*

MEDALS, seals, and articles of a similar nature may be produced by the aid of photography in the following manner:—A sheet of paper or glass plate is coated with a thick layer of bichromated gelatine, and this cake or film, when dry, is exposed to light under a positive; after printing, the soluble portions of the surface are washed away, and the film dried.

From the image in relief thus obtained an impression is taken by means of plaster of Paris, which is poured upon the matrix in a fluid condition after the latter has, in the first instance, been rubbed over with a little thin oil varnish. The plaster of Paris mould, when finished and dried, serves for the reception of an easily fusible alloy, which is poured in a molten state into the plaster form, and which then serves for a seal or other similar purpose.

These relief pictures generally possess the defect that the white portions, or highest lights, are far too prominent, and thus appear somewhat unnatural; but this is a fault that may easily be remedied afterwards. The relief becomes much more marked if care is taken to dry up the hollow cavities in the moist gelatine image by means of blotting-paper.

If it is desired, by means of the electrotyping process, to make a counter-mould of the plaster of Paris shape, the latter can be hardened by treatment with soluble glass

* De Navorscher.

(silicate of soda), which is brushed over its surface, and afterwards with a silver solution and sulphuretted hydrogen.

If the plaster of Paris is to be covered with graphite, it must, in the first instance, be saturated with warm wax or stearic acid. It is, moreover, necessary to cover the margin of the metallic surface with a pretty thick coating of wax, in order to prevent the action of the sulphate of copper solution, which otherwise would have an injurious influence upon the mould.

One of the best compounds to serve for producing electrotype prints, according to practical experience, is that suggested by M. Kress, of Offenbach, which is prepared by mixing together the following ingredients, viz. :—

White wax	7 parts
Asphalte	2 "
Stearic acid	3 "
Tallow	1 part

The asphalte is, in the first place, melted in a suitable vessel alone, and the wax, stearic acid, and tallow (which have been heated together in another utensil) are then added. As soon as all have been thoroughly mixed, as much fine black pigment is added as will impart to the mass a beautiful black tone; and finally, a small quantity of powdered plaster of Paris, and an equal amount of graphite, are added, to give more solidity to the compound.

The plaster form into which this mass is to be poured is previously placed in lukewarm water until air-bubbles cease to rise, a proof that the plaster of Paris is saturated with water. The form may also be saturated with lime-water if desired, but, in this case, it is necessary to coat the interior with oil before the mould is used.

NOTES ON DEVELOPMENT.

BY M. CAREY LEA.*

ONE of the last things that is acquired in the practice of photography is a knowledge of the exact relations which are required to subsist between exposure and development. Some never attain it; and even the most skillful often miss it. Perhaps the following remarks may prove of use to some, at least, of those who do not always succeed to their own satisfaction.

The badly lighted portions of a landscape indispensably require a certain prolongation of exposure, otherwise they cannot appear with proper detail in the development. The same is true in portraiture; but I shall direct these observations especially to landscape work, because the difficulty is there the greatest. In portraiture, the light can be varied and modified by the blinds, but in landscape work we must take the light as we find it.

If now other portions of the same subject are strongly illuminated, we are obliged to over-expose these. Of the two difficulties, of over-exposing the high lights, or under-exposing the shadows, it is, of course, always preferable to fall into the former, since it is possible to a considerable extent to remedy the evils incident to that course, whilst an under-exposure of the shadows is fatal.

The first precaution in these cases of great contrast is, of course, the use of a collodion containing a considerable amount of bromide. Having, then, used such a collodion, and having given a long exposure, let us consider the effects produced by a short and a long development respectively, with an iron developer of ordinary strength, say from fifteen to twenty-five or thirty grains of protosulphate to the ounce.

In consequence of the long exposure, the first application of the developer causes the image to flash out at once. If we at once cut this development short, and fix the plate, we get a clean, bright negative, which might, indeed, be suitable for making enlargements, but which, when printed in the ordinary way upon albumenized paper, yields a dark print, soft, indeed, but entirely wanting in force and character.

If, on the other hand, the developer be kept on the plate,

the image rapidly gains in density. If after thus prolonging the action we fix the plate, we have a negative that yields flat, light prints, as bad as, or worse than, the former.

Vary the action as we may, we always pass from one of these faults into the other. The prints are displeasing; the objects are not properly spaced out, but seem huddled together; the light and shade are displeasing; the effect is tame and characterless, by reason of want of contrast.

If now a tyro, finding this difficulty pressing upon him, consults authorities, he finds it always laid down that want of contrast proceeds from over-exposure. This is certainly true, but in a case like the present the information does not help him, but the contrary. For if he tries the effect of reducing the exposure, he obtains plenty of vigour, it is true, but falls into a new set of difficulties. If he gives a short development, his shadows are black and wanting in detail; if he prolongs it, the high lights become hard and blocky. One or other of these faults is certainly present, and in bad cases, both.

The remedy for these evils lies in regulating the developer. In cases like those which we have been considering, where a collodion with much bromide (that is, $2\frac{1}{2}$ to $3\frac{1}{2}$ grains to the ounce of collodion) has been used, and where the exposure has been prolonged, the sulphate of iron in the developer may be reduced to 10, or even 5, grains to the ounce.

This reduction, however, is not to be produced by simply adding water to the ordinary solution, because the acetic acid is not to be reduced in the same proportion, or, indeed, at all. But the five-grain solution is to have as much acetic acid to the ounce as the operator is in the habit of using with his ordinary developer.

Under such treatment the development becomes slower, and the high lights have time to receive a sufficient deposit of silver to produce the contrast necessary to give tone and force to the print.

The ideas involved in this explanation are very simple, and are known familiarly to very many experienced photographers. To many, however, they are not. The tendency at the present day is to give long exposures; formerly it was the other way, and one would hear the boast that such a negative was taken in so many seconds' exposure, as if that indicated anything. As time goes on, it became better and better understood that the object is to get the best possible result, not the best merely with any given means, but the best with any means that the photographer has the skill and talent to bring to his aid.

Generally speaking, the best negatives are not those that flash up under the developer, but those that come out quietly and regularly, neither springing out, nor, on the other hand, requiring much time and waiting.

A FEW REMARKS UPON BACKGROUNDS.

BY FRITZ LUCKHARDT.*

THE background is in the studio of the portrait photographer one of the most important objects, and has lately attracted very great attention in photographic journals, where the Salomon background has been much discussed. The construction of the uniform alcove background, as likewise the half cylindrical one recommended by Kurtz, of New York, must necessarily be attended with many difficulties; and, moreover, the application of both of them is a very limited one. The purpose of the Salomon background, for instance, is to render that part of the screen which is nearest to the light of a darker nature, so that the face of the model, which looks towards the shaded side of the studio, stands out in relief with greater effect from the other portion of the background. These backgrounds, irrespective of the difficulty in moving or shifting them, take up a large amount of space in the studio, and, in this respect, are much more inconvenient than simple stretched cloth backgrounds, that are easily moved to any position, and are, besides, useful for other purposes.

* Philadelphia Photographer.

* Photographische Correspondenz.

According to the nature of the illumination and character of the sitter, it is, in many instances, necessary to choose a dark or light background; and, for this reason, it is desirable that one should be in possession of a series coloured in different tints. The arrangement may be made to have a dark cloth stretched upon one side of a frame, and a light one upon the back, so that each stand serves two purposes.

The frames should be six and a half feet high, and five feet broad, and rest upon two iron supports two inches broad and one foot long, furnished with castors, so as to be easily moved about in the studio. As a matter of course, these serve only for bust and three-quarter pictures, as, for portraits of full length, the dimensions of these frames are not sufficiently large; and, furthermore, it is usual, in most studios, to use for such pictures backgrounds specially painted for the purpose. The accompanying sketch (fig. 1) shows the lower portion of a frame of the nature I have described.

FIG. 1.

Backgrounds of cloth, irrespective of their moderate cost as compared to painted screens, possess the great advantage that they are not easily damaged and stained, and their effect, when properly stretched, and the sitter is placed at some distance, is equal in every respect to these. In order to obtain the same effect that is at once produced by the Salomon background, I employ a moveable screen about three feet by three and a half, and place it as shown at *c d* in fig. 2—at an angle, namely, with the background *a b*—so that the side light is cut off, and the shadow of the screen, falling upon the background, forms the required gradation from dark to light. By inclining the screen, *c d*, at a greater or less angle behind, of course, the sitter, *e*, or between him and the background, the most varied shadows may be secured, provided always the cloth background is itself properly adjusted.

As portraits are generally taken with the sitter looking towards the darkened side of the studio, we should, in the case (say) of a blonde, find the hair come out better from the shadow, and the face more plastic from the lighted portion of the background. With sitters having dark hair, on the contrary, this manner of illuminating the background would be more seldom employed, as the model then sits with his face to the

FIG. 2.

light. In order, however, not to lose plasticity in the head, I would recommend the use of a strip of card about one foot broad and a foot and a half high, fitted on to a headrest stand, as in fig. 3, so as to be capable of being raised or lowered at will. This arrangement is placed behind the head of the sitter, the height of his forehead, at right angles, and close against the background, so that a shadow exactly like the one above described, but not higher than the forehead, is cast upon the background, and throws up the face, while the dark hair stands out in relief from the light cloth screen. In this instance, the larger screen, *c d*, referred to in fig. 2, is not, of course, used at all.

This arrangement will be understood on a reference to fig. 2, in which, in front of the background, *a b*, the small screen *g* is shown in position; the model is represented by *e*, and the camera itself is placed at *f*.

In order that the shadow cast by the small screen is not too sharp and decided, the upper part of the card is cut in the shape of a dome, and indeed,

in this way, the rounded shadow appears upon the background as if it were the natural one formed by the head of the model.

ON PHOTOGRAPHY IN THE PRINTING PRESS, BEING A DESCRIPTION OF THE WORKING OF THE HELIOTYPE PROCESS.

BY ERNEST EDWARDS, ESQ., B.A. (CANTAB).*

In previous processes of this kind, either a lithographic scraping pressure, or a copper-plate rolling pressure, has been employed. I have discarded both, and use in preference a simple vertical pressure, such as is obtained in an ordinary Albion printing-press. By this means I obviate the risk of displacing or scraping the film, and greatly increase its power of wear. The plate has now to be inked, and in this operation I have been fortunate enough to introduce an improvement which gives a value to the heliotype process, possessed, I believe, by no other printing method in existence. If in inking one of these plates, we use what is called a very stiff ink, we shall find that it will only adhere to the deepest shadows; if we thin down the ink we shall succeed in getting the delicate half-tones, but we shall no longer get depth in the shadows. This has been the notable fault with the productions of analogous processes; either shadows of intensity were produced with no half-tones, or half-tones were produced with no intensity. My method is to use two or more inks in succession, of different intensities, one after the other—to begin the picture with a stiff ink, and to continue it with a thinner. To produce different effects the colour of these may be varied. For instance, a stiff black may be used, which will give us the deeper shadows, and on the top of this may be rolled a thinner purple or brown, which will give us the half-tones. Many of the pictures on the wall are produced with two or three inkings, and you will notice presently what a very marked effect the double inking has in the production of the picture. This ability to produce a bichromatic effect in a single printing places a great power in the hands of the heliotype printer. In order to produce prints with a margin, so as not to require subsequent mounting, a mask of thin paper is made, having an opening in it exactly the size and shape of the finished picture. The plate having been duly inked, this mask is placed on it, and over the mask the paper on which the print is to be produced. The press having been pulled, the picture is peeled away from the plate with a perfectly clean margin, being, in fact, mounted. The dispensing with the cost and necessity for mounting gives this method of printing a great advantage, especially in the case of book illustrations; indeed, I may say in almost all cases. With the mounted print, as it comes from the press, comes also the end of the process. The prints have only to be looked over, and any slight casual defects remedied, when they are ready for issue.

There are two questions regarding the process that I am continually asked—how many impressions can be produced from one plate, and how many impressions can be printed in a day? In reply to the first, we have printed as many as 1,500 impressions from one plate without any loss of quality, and the plate was only then stopped because no more were required. From accidents to the films, however, we are by no means free. We have to bear in mind that though our films will stand any usage of the right kind, they will not bear the kind of usage that lithographic-stones or copper-plates are accustomed to receive; and we have, moreover, to bear in mind that in a new process everything, from first to last, has to be provided for in a new way—new materials, new hands, new appliances. At present, therefore, we cannot look for freedom from such accidents as novelty necessitates, but when I mention that a fresh plate may be prepared in an hour, at the cost of a few pence, you will see that these are of comparatively small moment. In numbers, one man will print between 200 and 300 impres-

sions in a day. As regards this point, it is to be borne in mind that a dozen subjects may be printed together, or the same subject laid down on the film a dozen times, so as to produce a dozen impressions at one pull. Compared with lithography, it will probably not be so cheap for large numbers, but for small numbers it will be cheaper, as the cost of drawing will be saved, and in either case the result will be far finer and more accurate. It is, of course, infinitely cheaper than any photographic or carbon process, or any other photo-mechanical process. Touching its applications, I need only point to the results which we have already obtained, some of which are on the walls for your inspection, to indicate many of them. But there are others equally valuable which we have not yet had opportunity of working. Amongst these latter, I may point to the use of heliotypes for pottery and enamelling purposes. It is only necessary to use an ink mixed with suitable oxides, and print on a suitable paper, to have on all descriptions of pottery, and at a lower price, pictures of art value in place of the anything but art pictures we are accustomed to accept. Again, this process provides a ready means of making prints in suitable ink for transfer to stone or zinc, or to wood for the purposes of the wood engraver. Having for its base a coloured, or partly coloured, design, a new kind of photo-chromo-lithography is within reach. But the direction in which I conceive it has the greatest value is in the artistic and scientific education of the people, where it affords a means of bringing within the reach of all, reproductions of works of art and records of science which would be otherwise unattainable.

It is true that the reproduction of drawings by such men as Raffaele and Michael Angelo contain the inevitable faults of the photograph produced by their discolouration from age; nevertheless it is impossible to look at some of these—such, for instance, as the heads and bands of two of the apostles for the painting of the "Transfiguration," by Raffaele, or a sheet of studies of heads by Michael Angelo—without feeling that you have there the veritable work of the master—that his hand alone, that no other hand but his, has produced the copy as well as the original. In point of price, there is no reason why pictures such as these should not take the place of those which, at present, are used to decorate even the walls of cottages.

It is true, too, that, as in all processes depending on a photographic negative for their base, colour is unfaithfully reproduced. Hence, oil-paintings depending on colour for their effect, require an intermediate translation. A copy must first be produced wherein the defects so arising must be corrected, and this copy must then be again reproduced for issue. It seems to me probable that as progress is made there will be a distinct class of artists, who will be "translators of colour into light and shade" for use in this and analogous processes. Where paintings depend for their effect on light and shade or form, and not on colour, this intermediate translation is not so necessary. It is pictures such as these last of which we are accustomed to say that they photograph well.

For the reproduction of old or rare prints or engravings, this process is especially valuable, or for the reduction and enlargement of existing ones. Where there is a copper-plate in good preservation, there is obviously no point in the use of any repeating process, for there is the certainty that there can be no gain of work by the operation of photography. But where a reduction is desired, or the plate is destroyed, such a repeating process as this comes in with overwhelming force. To the inevitable question, will not engraving be superseded? I would say, no; engraving is an art of itself, and, as such, can never die. But one of the special objects that all workers in this direction have in view is, to supplement engraving. Engraving is a costly and a tedious process. The execution of one of the great engravings will occupy years of time, and cost thousands of pounds. In the Academy exhibition of any year, how many pictures are engraved? And in pictures that are engraved, has not the interest in them greatly ceased when

the engraving is issued? Surely here, then, there is room to supplement engraving with some means for issuing swiftly permanent and faithful reproductions of works of art contemporaneously with their exhibition. I venture to think that English artists have a lesson to learn in this respect from the French, who find their account in publishing photographs of their work in such a manner.

For book illustration, the heliotype process is especially valuable. The rate of production is rapid and certain, the cost is moderate, and the necessity for mounting is done away with.

For scientific record it is equally valuable. It retains the literal faithfulness of the photograph, and is, moreover, permanent, and far cheaper.

We are not slow to recognise in every direction the value of the photographic art, with its many drawbacks. The heliotype process, in a word, is an attempt to put this art into the printing press.

(To be continued.)

CONVENIENT DRY PROCESS.

BY PROF. J. TOWLER, M.D.*

The following dry process is one which I have used during the past summer for taking views at no great distance from any resting-place I might select for residence, and then walking or riding out with camera and changing-box for a mere excursion. It works well.

The plates are first well washed and coated with a thin film of albumen (one ounce of albumen to ten or twelve ounces of water, and one drachm of ammonia).

When dry, the plates are coated with collodion, and sensitized in the usual way until the film has assumed a creamy appearance. It is always better to prepare the dry plates in the evening by candlelight, and then place them in the drying-cupboard, so as to be ready by the next morning for the excursion. As soon as each plate is properly sensitized, it is placed, film downwards, in a large wash-basin full of rain-water until the next plate is ready; it is then taken out and washed thoroughly at the tap with rain-water, and floated with the following preservative:—

THE PRESERVATIVE SOLUTION.

Albumen	4 drachms
Water	5½ ounces
Gum arabic	15 grains
Acetate of morphia	5 "
Acetic acid	2 drachms

Mix these ingredients intimately together, and keep in stock for use. Previous to application, filter the amount required.

Each plate is flowed or coated with just enough of this solution so as to cover it thoroughly. The solution is flowed backwards and forwards over the plate for about a minute, and then the excess is allowed to drain off, after which the plate is put away in the drying-cupboard or box to dry.

EXPOSURE.

Expose the plate three or four times longer than you would an ordinary wet plate—sometimes even longer than this. It is well to dry one of each batch before you start off on the excursion, in order to be able to form some judgment as to the exact exposure that will be about right.

DEVELOPMENT.

First moisten the plate in a dish of rain-water; afterwards flow over it a drachm or two of the ordinary nitro-gelatine developer. This developer is then returned to a small beaker glass, and about two drops of nitrate of silver solution are added, and intimately mixed with it. This is the developer proper, which is again poured upon the plate.

* Philadelphia Photographer.

The picture now soon appears, and may be strengthened to any amount by adding more silver solution. There is no fogging in the picture thus produced, and the detail is all that can be desired.

I do not know how long such plates will keep, and I must confess that the keeping property is of minor importance to me, from the fact that I have ceased to run any risk with dry plates by using them, except on the day after their preparation at the longest. In this way there is a possibility of getting good, even superior, work with considerable convenience and certainty.

Correspondence.

THE GRAPHOGENIC APPARATUS.

DEAR SIR,—Will you allow me space for a few words in reply to your correspondents, and in answer to numerous enquiries respecting the use of my new apparatus for out-door photography. In the first place, with regard to the sensitizing bath, some fears have been expressed as to the suitability of the materials employed in its construction. In this respect there is more fear than danger; it has been proved by several years' experience that wood properly varnished with shellac is an efficient substitute for glass or porcelain when used as a receptacle for the nitrate of silver solution. The same remarks will apply to the india-rubber lining. I wish it, however, to be understood that I do not confine myself to the use of the latter substance, and have described in my patent several other methods of transferring the sensitive plate to the dark slide by which the india-rubber is entirely dispensed with; an arrangement which would probably be found necessary in extreme climates; but for general convenience and economy I think the india-rubber is preferable.

The mode of development in a dish is very similar to that described recently by Mr. England in your pages; this method has been for many years extensively used on the continent.

As regards keeping the plates moist after development, where they have to be kept only a short time, the acetic acid solution will be found all that is necessary; but in cases where the negatives are required to be kept for a long time previous to fixing and intensifying, it will be advisable to give a second coating with the golden syrup preservative recommended by Mr. Robinson, by means of which the negatives may be kept for weeks or even months in an ordinary plate box without injury; but care must be taken to apply the golden syrup *after* removing the plate from the developing tray; the slightest trace of such a powerful restrainer in the dish would be fatal to the development of the next picture.

In coating plates with collodion in the open air it is a good plan to dilute the collodion with a little absolute alcohol or a mixture of alcohol and ether; with this precaution no difficulty will be experienced in this part of the process.

Trusting I have not trespassed too much on your space,—I am, dear sir, yours very truly,

B. J. EDWARDS.

Hackney, May 15th, 1871.

COPYRIGHT IN PORTRAITS.

STR,—Since my last letter to you, two cases of prosecution for infringement of copyright have been decided; one at the Mansion House, the other at Worship Street.

In the former, Mrs. T. Conroy was convicted, and ordered to pay penalties amounting to £35; or, in default, to suffer nine months' imprisonment. As this matter is under the consideration of her solicitor, with a view to remove the conviction into the Court of Queen's Bench, I will make no remarks upon it at present.

In the latter case, Mr. Knight, of Tabernacle Walk, was convicted of selling an illegal copy of a photograph representing the Oxford crew, and fined £5. The circumstances, as detailed in evidence, are shortly as follows:—

The proprietor of the copyright (Mr. Taunt) visited Mr. Knight's shop, and purchased from him one copy of his photograph of the crew, and asked Mr. Knight to procure him six more. Mr. Taunt gave a feigned name, and an address to which they were to be sent. Mr. Knight, not feeling certain about the copyright, did not execute the order. On receiving

the summons, Mr. Knight determined to defend himself instead of employing a solicitor, as the matter was not of much importance. I attended the hearing to hear the argument, and assist Mr. Knight, if necessary, in his defence. Mr. G. Lewis appeared for the complainant; and, at the conclusion of his case, Mr. Knight made his statement, from which it appeared he had purchased the copy for which he was summoned from Thomas Conroy, a boy about twelve years of age, son of Mrs. Conroy, of whom he enquired whether there was any copyright. The boy replied there was not. This copy Mr. Knight placed in his window, and afterwards sold to the plaintiff; that was the only copy he had. I then suggested to Mr. Knight to make certain objections to the registration and copyright.

Mr. Knight first objected that the description of the nature and subject of the work was insufficient. Mr. Lewis here rose, and, addressing the magistrate, said there was a gentleman present, Mr. Cunningham, who was at the bottom of all these defences, and who was now advising the defendant. He was not a solicitor, and had no right to interfere, particularly as, on a former occasion, when the defendant was summoned to this court, Mr. Cunningham's conduct was the cause of some very severe remarks being made by the magistrate who heard the case. Upon Mr. Bushby replying, "I don't see that, Mr. Lewis," the learned gentleman subsided, and the case proceeded. Mr. Knight's objection to the sufficiency of the description was overruled.

Mr. Knight next objected that the copyright (if any) was vested in the sitters, and not in the photographer; and that there had been no assignment of their rights to the complainant. As Mr. Knight did not put this objection very clearly, the magistrate did not quite understand it.

Mr. Lewis then rose to explain it by reading the first section of the Act. Commenting upon the words, he said: "When a photographer takes a portrait of a sitter for a good or valuable consideration, doubtless the copyright vests in the sitter; but, in this instance, there was no valuable consideration; nothing was paid by the sitters, *therefore the copyright vests in my client,*" a non-sequitur which, to my surprise, the magistrate accepted. It does not follow that because the copyright is not in the sitter that it is in the photographer.

We have now a magisterial decision upon a very important point: the proposition is established, so far as such a decision can establish it, that in all cases where photographers take negatives without receiving payment, the copyrights thereof vest in the photographers. What will the Society of Arts and Mr. Le Neve Foster say to that? By the common law an individual has a right to his own face and all pertaining to it, and no power save that of an Act of Parliament can deprive him of that right.

Let us suppose a case as an illustration. Mr. Blank, being desirous of having his portrait taken, calls upon Mr. Cyanide, and agrees with him to have a negative taken, and so many copies printed, for a price. Mr. Cyanide takes two negatives, from which Mr. Blank chooses one. The proofs are printed, and, with the negative, are delivered to Mr. Blank, who thus becomes the owner of the copyright. A few days afterwards, Mr. Blank, passing Mr. Cyanide's establishment, to his surprise sees his portrait "gibbeted upon the advertising door-post." Feeling annoyed thereat, he accuses Mr. Cyanide of infringement of copyright. "Oh! dear no," says that gentleman; "the portrait you see has been printed from the other negative, and for which you did not pay; therefore, by a decision of Mr. Bushby, at Worship Street, the copyright thereof is vested in me during my lifetime, and for seven years after my death in my representative, and I have registered it at Stationers' Hall." Mr. Blank then consults his solicitor, and by him is, probably, informed that he has two remedies, Mr. Bushby notwithstanding: he may apply to a court of equity, and obtain an injunction, or he may apply to a court of law, or a judge, for a rule or summons requiring Mr. Cyanide to show cause why the entry at Stationers' Hall should not be expunged.

In the case of "Colonel" Burke, the Secretary of State ordered a photograph to be taken of him at the House of Detention, which was done, and the photographer registered the photograph. The taking of the photograph being an invasion of Burke's common law right, his representative took steps to suppress the photograph by summoning the photographer before Mr. Justice Willes, who made an order to expunge the entry at Stationers' Hall, condemned the photographer in the costs, and ordered him to give up the negative and all copies in his possession.

Suppose some disagreement were to arise between the Oxford crew and Mr. Taunt respecting the photograph; the crew would have the power to prevent the further publication of it, their verbal consent to its publication not being an assignment of their rights.

As to what constitutes a good or valuable consideration may be doubtful. In the case of a Royal Duke, Mr. Commissioner Kerr held that the sitting of His Royal Highness to the photographer was a valuable consideration.

At Waudsworth, in the matter of John Bright's portrait, Mr. Merriman argued that Mr. Bright's sitting was a valuable consideration, sufficient to vest the copyright in Mr. Bright, and Mr. Dayman appeared to accept the validity of that argument, and I believe that if the prosecution had not been abandoned, he would have so held. When eminent persons sit to photographers, doubtless they believe that they can at any time order the publication thereof to cease if they think fit, in the same way as they might if they themselves had published them. It is not likely that when the Oxford crew sat to Mr. Taunt they contemplated investing him with such a power as would enable him to cause a poor woman having a family of ten children to be sent to gaol for nine months for selling eleven copies of their portraits to Mr. Taunt. The opinion of Mr. Bright upon this kind of prosecution has already appeared in your columns.

The term "copyright," by the interpretation clause of the Act, is defined to be "the sole and exclusive right of reproduction;" it therefore follows that unless an individual have that sole and exclusive right, he has not copyright.

I think I have said enough to show that no photographer has the "sole and exclusive right" in any portrait without an assignment of right from the sitter, and there was no assignment in this case. Mr. Bushby having over-ruled the objection that there was no copyright vested in the complainant, gave judgment; he said he was called upon to convict the defendant of having sold a copy of a photograph knowing it to have been illegally made; the defendant excused himself by saying he did not know the photograph was copyright; if that excuse is to prevail, then nobody would be punished. The Act provided that a register of copyrights should be kept at Stationers' Hall, and it was the duty of the defendant to have gone there and ascertained whether the photograph were copyright. Now, with all deference to the magistrate, the defendant's going there would have been useless. The first question the clerk there would have put to him would have been, "What is the name of the author, and the name of the proprietor, and what is the title of the work?" Just what the applicant wanted to discover. The photographer who made the copy might have had a clue, because the name of the author may have been upon the mount; but that even might be misleading, for I have seen mounted upon cards bearing the names of two eminent firms, and marked "copyright," photographs of certain ladies whose attire might be said to resemble nearly that of a French actress performing the part of Eve, and which was described as consisting of nothing in particular beyond a belt and a buckle. I should certainly not have felt justified in concluding that these photographs were really produced and published by the firms whose names were upon the mounts. The magistrate ordered Mr. Knight to pay to the complainant the sum of £5, which, I suppose, he considered to be about the amount of damage sustained by the complainant through the act of Mr. Knight, or, in default, to be imprisoned for the period of two months, under the "Small Penalties Act."

Sancho Panza invoked blessings upon the man who invented sleep, and surely publishers should do the same upon him who discovered that the "Small Penalties Act" was applicable to the punishment of the civil offence of infringement of copyright. Some one has said, "Law is the perfection of reason." He either used the words ironically, or he must have been ignorant of the mode in which (what is called) justice is administered by magistrates; for what can be more unreasonable than to send a man to prison for the invasion of a private privilege, under the provisions of an Act of Parliament passed as a supplement to the "Wine Licenses and Refreshment Act," and for the purpose of restraining magistrates from inflicting upon drunken and riotous persons a longer term of imprisonment than the justice of the case might require? I would recommend magistrates to read the encomiums made upon them by Lords Redesdale and DeMaui (who opposed the Bill) respecting the great care and discretion exercised by them in apportioning fines to the circumstances of the defendant, and then

consider how far they deserve them when they send a poor woman to prison for nine months—a proceeding entirely at variance with the spirit of the Act, which was passed to abridge the power of the magistrate, and not to increase it.

I shall, in another communication, give you an account of the origin and purpose of the "Small Penalties Act," which has been made a means of cruelly punishing persons who were not in a position to protect themselves from magisterial vindictiveness.—I remain, sir, your obedient servant,

J. CUNNINGTON.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held in the City of London College on the evening of Thursday, May 11th, the Rev. F. F. STATHAM, M.A., in the chair.

The minutes of a former meeting having been read and confirmed,

The CHAIRMAN remarked that, in accordance with a previous announcement, the evening would be devoted to an examination of such photographs as members had brought for exhibition, and conversation thereon.

The contributions to the interest of the exhibition meeting were less numerous than on some former occasions, but many fine photographs were placed before members. Mr. Price exhibited a number of his fine landscapes by the collodio-albumen process. Mr. Dunmore showed excellent landscapes and studies. Mr. Hunter exhibited a fine selection of prize pictures of the Amateur Photographic Society. Mr. Croughton showed some fine coloured photographic miniatures, and works showing the aid photography affords to art. Mr. Johnson showed some very magnificent carbon reproductions about 4 feet by 3 feet, and gave some details of their production at the establishment of the Autotype Company. Mr. Henderson showed some of his fine enamels. Mr. Wharton Simpson exhibited some fine American portraits of a clever little *genre* picture by Rejlander. A general conversation on the pictures was maintained, after which the proceedings terminated.

Talk in the Studio.

POSTAGE STAMPS FOR SMALL REMITTANCES.—Our attention has been called to the possible inconvenience to photographers of the proposed arrangement of the Postmaster-General, prohibiting postmasters to purchase postage stamps of the public, in order to check the use of stamps for small remittances. As the matter stands, the Postmaster-General has announced that after June 30th postmasters will be prohibited from cashing postage stamps, and that money orders for small sums at a cheap rate will be issued. The use of stamps for transmitting small amounts is, doubtless, very convenient, and to photographers and photographic dealers, as to many tradesmen it has, doubtless, been of considerable service. To no class will the withdrawal of this facility prove more inconvenient than to newspaper proprietors and their customers, between whom stamps had become common currency for small sums. The matter has already been brought before the attention of the Postmaster-General, and it is probable the decision may be reconsidered. A deputation from the Provincial Newspaper Society waited recently upon the Postmaster, and called attention to the inconvenience of the new regulation. He explained that the real object of the regulation respecting the sale of postage stamps was to check the robberies of post letters; but on that point, as well as on others which had been brought under his notice, he would, if possible, meet the views of the newspaper proprietors. The abuse of the system, in making payments beyond two or three shillings, has doubtless contributed to bring about its threatened prohibition.

COMED MEDALLIONS AND VIGNETTES.—Mr. A. D. Lewis, of Newcastle-on-Tyne, has favoured us with some exceedingly fine examples of cameo portraits, card, and whole-plate size, which he has been producing with success for twelve months past. The photography is excellent, and the surface is enamelled with gelatine and collodion, which, in the cameo style, gives a greatly improved effect. He remarks that the style has been "a great success with me, and considerably stimulated my business during last summer, and all through the winter months. I produce them in any desired

tints, just to suit the taste of the public. I never get less than thirty shillings a dozen for such as the enclosed, and for half-a-dozen of such, and half dozen full-length, twenty-one shillings. Even for the plain cameos I get at least a third more than the ordinary price, and out of every twelve sitters, eight or nine prefer the 'cameo vignettes' which shows that the profession ought to take advantage of this beautiful style of portrait as an impetus to business. I produce various tones, but my customers prefer the warm purple brown tones. I will send you a few coloured enamelled ones by-and-bye." The whole-plate example has, we understand, been exposed in a show case for twelve months, and retains its convex shape perfectly.

SIR JOHN HERSCHEL.—The place chosen for the internment of the late Sir John Herschel in Westminster Abbey to-day, Friday, is close to the grave of Sir Isaac Newton, at the extreme east end of the nave, near the organ screen.

TINTED PAPERS.—Mr. A. Rivot has sent us some examples of portraiture and landscape on tinted paper he is preparing. As we have before remarked, tinted paper is often very effective when judiciously selected, and these tints are very good. A delicate warm pink, tending to buff, is very pleasing for portraiture. Mr. Rivot also mentions that he undertakes for photographers who have not facilities for the work, the ombossing into form of cameo vignettes. This facility may prove useful to those desirous of trying the new style without risking at the commencement the cost of the press and other aids required.

PHOTOGRAPHY AND THE COLUMN VENDOME.—Just before the fall of the Column Vendome in Paris, photographers were very active in their operations on the square, taking the portraits of patriots grouped on a portable barricade. Another was at a window of one of the houses on the east side of the square, taking a last view of the Column. There was also an artist there, engaged in sketching the scene; and behind him were two more photographers—a man and a woman—exerting themselves in the same direction. Thus it is, by the invaluable aid of photography, the public are enabled to obtain pictures of these notorious places.

To Correspondents.

CAPTAIN.—You would be liable to proceedings for copying and selling the engravings of the *Illustrated London News*, *Graphic*, and similar papers, without permission from the owners.

A. CLARKE.—You will find our opinion on another page. Your rule is a good one; but it would be safe to extend it to gentlemen as well as ladies. Thanks for the instructive and interesting prints.

CAPTAIN TURTON.—The plan of printing through a medium consists in interposing a thin plate of glass or other transparent body between the negative and the sensitive paper, and printing in direct sunlight, for the purpose of securing a print with softened definition. It has been repeatedly described in the *News*. You will find a fully descriptive article on page 243 of our thirteenth volume, and another on page 73 of our fourteenth volume. 2. Prints should be very slightly damp when ironed; but with some samples of highly albumenized paper ironing always causes the prints to curl. It is better always to iron the back of the print. 3. The sulphocyanide bath given in the *Year-Book* is one we have often used with success. The prints may be immersed without washing, or after slight rinsing. The sulphocyanide bath often works somewhat slowly; but we have not found it reduced the prints. It can be made to work more rapidly by the addition of a few drops of a concentrated solution of chloride of gold. 4. We do not know of any one who undertakes printing in carbon from the negatives supplied by photographers.

WILLIAMS.—We should decidedly recommend No. 3. So far as our information and experience goes, No. 1 is somewhat uncertain; never superior to, and rarely equal to, No. 3. We should recommend you to look out for a second-hand one of No. 3, which will be quite as good as new, and cheaper. Read the advertisements of that kind in the *News*, or advertise for what you want. The advertisement will cost you 3s., but you will probably get what you require without difficulty, and save as many pounds. We approve of your resolution, and are glad to hear of your progress.

VIGNETTE.—The studio of Col. Stuart Wortley was described and figured in the *Year-Book* of 1864, where several other studios are described, and diagrams given.

ARTHUR THOMPSON.—Streaks in the direction of the dip may proceed from various causes. Sometimes they are the result of a bath charged with organic matter; sometimes they arise from the collodion. They may generally be avoided by keeping the plate in motion, especially lateral motion, all the time the plate is in the bath.

FRED. WRIGLEY.—The copying of old oil paintings is always a difficult task, the more so if the work is heavily impasted and the varnish cracked. In the first place, you must have the picture well lighted, and with a light directly in front of it; a light coming from a source across the surface will bring out all the inequalities of texture in a disastrous manner. You will get it lighted best in the open air: some prefer direct sunlight. To get rid of the dullness of surface which often renders it difficult to get detail, sponge the surface with water immediately before exposure. To avoid reflections, try two or three positions, and take care that the camera is quite parallel with the picture; a fully bromized and ripe collodion, very full exposure, and ordinary iron developer. It is, as you observe, a branch of the art little practised, and one in which experience and varied resource are very necessary.

A BEGINNER.—There is certainly some slight risk to the bath in immersing a plate in it the edges of which have been varnished; but we should not recommend you to try the process you mention, as it is one of very uncertain success.

F. D.—There was no print enclosed in your letter, but, from the description you give of the defect, it seems probable that it arises from a repellent collodion. You may modify this tendency in a variety of ways, but it is at times difficult to cure. The addition of a drop or two of distilled water to each ounce of collodion will sometimes improve matters. Immersing the plate as soon as possible after the collodion is set will improve matters. Keeping the plate in motion in the bath, and giving a time in the bath, will improve matters. Sometimes nothing but age, or mixing it with a more powdery collodion, will improve it. 2. The use of a ripe collodion of good body, of an iron developer containing a little gelatine or acetate of iron, so as to secure a clean intense image in the first place; then, after fixing, apply a ten-grain solution of bichloride of mercury until the film is of a uniform grey, wash, and apply a one-grain solution of iodide of potassium. This will give an intense but delicate image, without much piling up. 3. It is always difficult to clean perfectly plates which have been used, and there is generally some risk in using the plates; but we do not think that the case is worse with negatives which have been intensified with mercury than with other plates. The preliminary coating of albumen removes much risk.

S. W. BARNES.—The minute spots of which you send samples are very difficult to trace home. Sometimes they are due to minute air-bubbles forming on the print during fixation, but not always. A skillful experimentalist, who has been giving some attention to the subject, traced them to some kind of decomposition in the paper, arising from age. A sample of paper which gave him spotless results in the course of time began to spot, and, after keeping six months, was covered with such spots; whilst a new sample, used under the same conditions, was perfectly free.

J. C. MOORE.—The acetate bath answers well for producing warm tones. To make an acetate bath take—

Chloride of gold	1 grain
Acetate of soda	30 grains
Water	5 ounces

and use not less than forty-eight hours after mixture. This may be used over and over again until the gold is exhausted.

C. A. M. W.—The plan you propose will doubtless answer. The acid, although it stops development, will not, we apprehend, prevent the slight additional intensification effected by light. If once the film has been suffered to dry, we should prefer to fix it, and intensify after fixing. With Tunicare or albumen preliminary coating, varnishing the edge will scarcely be necessary (see Mr. Edwards's letter in the present number).

JOHN TERRAS.—We are glad the pictures pleased you. We doubt whether cards or cabinets by the gentleman you mention can be readily obtained, as he does not publish, and photographers rarely sell private portraits. His speciality is, moreover, for larger pictures. Your best plan will be to write to him direct.

ENQUIRER.—In a ridge-roof studio of good proportions, with a principal north light, glass is not necessary. Sometimes, especially in small studios, it is desirable to have a little. There should be no glass at either end. The following are good proportions:—26 ft. long; 12 ft. wide; height to eaves, 8 or 9 ft.; to ridge, 14 ft.; opaque at both ends and south side; opaque for 5 or 6 ft. at each end of north side and roof; all the rest glass, except 18 in. at bottom of north side.

A. DEBENHAM.—We will look for the pictures you mention, and give them attention in our notice.

A. START.—Much depends upon whether you want a thin or thick varnish. We should say about 40 grains per ounce. Methylated chloroform will serve perfectly. 2. Bates' black varnish will answer for the lens tube; but an absolutely dead black is better.

R. LAMBERT.—If you wish to take the four portraits of the diamond cameo portraits on one negative, you require a repeating back for the purpose; but you can take them in succession, and mount them separately, if you wish. 2. For the cameo vignettes now in vogue no registration cards are necessary. 3. We believe that the Autotype Company supply the manual under some conditions gratuitously.

Several Correspondents in our next.

STRONG AND WEAK IRON DEVELOPERS.— STOCK SOLUTIONS.

THE importance of a perfect understanding of the effect of every modification in the developer, and its use gives a perennial interest to the subject, and renders every hint which can extend the range of the photographer's power over his materials worthy of attention. On another page a correspondent asks a series of questions on the subject which suggest a few general observations, as well as definite answers to his questions.

The first question arises out of a discrepancy, probably more apparent than real, between the views of Mr. Carey Lea and Mr. Elbert Anderson, as to the use of strong or weak iron developers for subjects containing strong contrasts. Mr. Lea suggests that in landscapes containing much contrast in the shape of deep shadows or portions badly lighted, in conjunction with other parts strongly illuminated, the use of a highly bromized collodion, full exposure, and very weak iron developer, will best secure detail in the shadows and vigour in high lights. Mr. Anderson informs his pupil that if a sitter presents strong contrasts—such as those found in the lady, presumably fair, named Aurora, and her black velvet dress—he would give full exposure, and use a strong developer, reserving the weak developer for the same lady when she appeared dressed in white drapery and lace. It is probable that Mr. Lea would do the same; and that, when writing, he had in his mind's eye some especial landscape, with masses of well illuminated detail, and small portions of imperfectly lighted shadow. The latter he hoped to bring out by the combined effect of full exposure and prolonged development, during which the masses of well lighted detail would be saved from becoming flat by the weak developer. Full exposure, and prolonged application of a strong iron solution, would inevitably produce flatness in masses of well lighted landscape, whilst the same conditions with a weak developer would secure brilliancy. Special cases require special treatment, which can only be devised in definite relation to the circumstances as they arise; but it is important to remember the rule that, other things being equal, strong developers tend to produce equality or evenness in the deposit of silver, and so tend to harmonize strong contrasts; whilst weak developers facilitate an aggregation of deposit on the lights, and so increase contrasts. If the lighting and combination of colours in the subject present little contrast of light and dark, a weak developer will produce the most brilliant result, because it will pick out the high lights, and give them a decided distinction from the half lights; whilst the shadows or darks, which in the subject are wanting in force, receiving less silver in proportion than their share, will acquire relative depth. The same subject developed

with a strong iron developer would become flat or weak; the silver, being deposited in equal ratio over lights and shadows, does not aid in producing contrast, and a poor, spiritless picture is the result. If the lighting and combination of colours in the subject tend to produce strong pictorial contrast, a strong developer will check the tendency; the silver will be thrown down fairly on the darks and imperfectly illuminated portions, and hence cannot accumulate on the lights and give them increased intensity, harmony, rather than excessive contrast, being the result. A weak developer in such a case would be apt to give chalky high lights without the delicate demitints which give tenderness and black shadows, without detail or transparency. As a rule, the longer the development necessary to bring out the image, the greater will be the contrast and intensity, as the free nitrate on the plate is precipitated by the reducing agent most readily upon the portions where light has acted most energetically, and continues to aggregate there so long as the process is prolonged and any free nitrate remains on the surface. When, either through length of exposure or strength in the developer, the whole image rapidly flashes out, there is a tolerably even deposit of silver; and, other things being equal, the picture is harmonious. When, through imperfect illumination, short exposure, or weak developer, the image comes out tardily, there is always risk of excess of contrast and hardness.

Our correspondent further asks what constitutes a strong developer in contradistinction to an "ordinary" developer. The latter term, it must be confessed, is somewhat indefinite, and admits of a wide definition. In our own practice we should speak of a fifteen or twenty-grain developer as one of ordinary strength, and one of twenty five grains or upwards we should regard as strong. With a fifty grain developer containing about twenty minims of acetic acid to each ounce of solution, it is possible to very materially reduce the exposure where the nature of the subject does not seriously suffer from such forcing. With portraits of babies and animals, for instance, very good results may be produced.

The use of a saturated stock solution of iron presents many advantages, and has no especial defects to counterbalance the gain. Properly made and kept, the solution will keep perfectly without deterioration; many operators, indeed, allege that the solution acquires special virtues not to be secured by other means. The only disadvantage likely to arise is the peroxidation of a portion of the iron salt, and this not only robs the solution of active reducing power, but introduces a positive retarding agent, more active than acetic acid. This duly allowed for in preparing the solution is not a serious defect; but it is important that full allowance should be made, or the effect of under-exposure will be inevitable. If a saturated

solution of protosulphate of iron be made with water containing carbonate of lime, and the water be warm, a portion of carbonate of iron is formed, and if acetic acid be added, the formation of acetate of iron follows. Indeed, if acetic acid be added under any circumstances to a solution of sulphate of iron intended for keeping, a portion of acetate of iron is generally formed. In reference to the question often asked, how many grains per ounce does a saturated solution of protosulphate of iron contain? it must be borne in mind that when the point of saturation is obtained, a slight variation of temperature changes the strength. A saturated solution made in the heat of summer will throw down crystals of the salt it cannot hold in solution in winter. A perfectly saturated solution contains at a temperature of 60° Fah. rather more than forty-one parts of the salt in one hundred parts of water, or nearly two hundred grains of the salt in each ounce of solution.

To make a saturated solution, take five drachms and a half—or, in order to have a little excess, say six drachms—of protosulphate of iron for each ounce of water. Thus, one pound of the iron salt will be required for each pint of water. To facilitate solution the salt should be powdered, the water should be used cold, and no acetic acid need be added. The bottle should be well corked, and kept in the dark, resting on its side, or with the cork inclined downwards. If a brown deposit be formed, it should be filtered out before adding acetic acid, unless the operator desire to form a portion of acetate of iron in his developer.

The use of such a solution is very simple. An ounce and a-half of such a solution, added to eighteen ounces of water and five drachms of acetic acid, will give a pint of the ordinary fifteen-grain iron developer. Without any trouble beyond measurement, a developer of any degree of strength is thus secured at a moment's notice. A child has moved, for instance, and the operator was compelled to remove the plate with, perhaps, half the exposure desirable; half an ounce of the saturated solution, an ounce and a-half of water, and about a drachm of acetic acid supply at once a couple of ounces of a fifty-grain developer to meet the short exposure; and so with any varying condition of light, exposure, or subject, the facility for modifying the developer without delay or trouble will often prove invaluable in rendering work pleasant and results excellent.

The addition of sulphate of copper, frequently recommended as valuable in the iron developer, is found useful by Mr. B. J. Edwards, who uses a concentrated solution in preventing the stock solution from oxydizing. The precise action of sulphate of copper and sulphate of zinc in the iron developer has not been clearly made out; but that they exercise a restraining effect in development, rendering the reducing action of the iron salt less violent, has been made tolerably certain in general practice, and Mr. Edwards states, from observation, that the action of the copper salt prevents the oxidation of the iron solution is beyond a question.

NOVEL METHOD OF ENGRAVING FROM PHOTOGRAPHS.

A SINGULAR and altogether novel method of obtaining engraved surfaces from photographs is announced in a recent number of the *Journal of the Franklin Institute*. It is based on a discovery by Mr. B. C. Tilghman, of Philadelphia, of a new method of cutting, grinding, and engraving metal, stone, glass, and similar hard substances. The method consists in driving a jet of fine sand against the substance to be cut. Mr. Coleman Sellers, in describing the process, says:—

"A jet of quartz sand thrown against a block of solid corundum will bore a hole through it $1\frac{1}{2}$ inches in diameter, $1\frac{1}{2}$ deep, in twenty-five minutes, and this with a

velocity obtainable, by the use of steam as the propelling power, at a pressure of 300 pounds per square inch—a remarkable result, when we consider that corundum is next to and but little inferior to the diamond in hardness."

He proceeds further to mention that glass can be ground or depolished in this way more easily than by any other method, and that "by covering parts of the glass surface by a stencil or pattern of any tough or elastic material, such as paper, lace, caoutchouc, or oil paint, designs of any kind may be engraved.

"There is a kind of coloured glass made by having a thin stratum of coloured glass melted or 'flashed' on one side of an ordinary sheet of clear glass. If a stencil of sufficient toughness is placed on the coloured side, and exposed to the sand blast, the pattern can be cut through the coloured stratum in from about four to twenty minutes, according to its thickness.

"If a current of air of less velocity is used—say about one inch of water—very delicate materials, such as the green leaves of the fern, will resist a stream of fine sand long enough to allow their outlines to be engraved on glass. By graduating the time of exposure with sufficient nicety, so as to allow the thin parts of the leaves to be partly cut through by the sand, while the thicker central ribs and their branches still resist, the effect of a shaded engraving may be produced.

"The grinding of such a hard substance as glass by an agent which is resisted by such a fragile material as a green leaf seems at first rather singular. The probable explanation is, that each grain of sand which strikes with its sharp angle on the glass pulverizes an infinitesimal portion which is blown away as dust, while the grains which strike the leaf rebound from its soft elastic surface.

"The film of bichromatized gelatine, used as a photographic negative, may be sufficiently thick to allow a picture to be engraved on glass by fine sand driven by a gentle blast of air."

A subsequent number of the *Journal* adds the following:—

"In the interesting description of 'Tilghman's process of cutting hard substances,' by Mr. Coleman Sellers, in our last issue, the fact that printing from the bichromatized film could be accomplished in this surprising manner was mentioned. Since the article has appeared, Mr. Tilghman has devoted his time and attention to the development of this branch of his fruitful discovery, and with great success. We have been favoured at his establishment with the opportunity of examining several specimens of his new art, which were sharp and beautiful reproductions from the negative."

To what perfection this method may be brought, and how far it may have specially useful applications, we cannot at present even conjecture; but it is certainly one of the most novel modes of engraving a photograph yet brought before the public.

VICISSITUDES OF A PHOTOGRAPHIC PORTRAIT.

NOTWITHSTANDING that photographic portraiture is always regarded a fair game for the ready sneer in literature, in court, and in the senate, the trustworthiness of its record, and the tender associations necessarily belonging to its absolute identity and relation to the sitter, constantly receive almost unconscious testimony. We have recently received from Mr. James Brown, of Otago, a couple of New Zealand papers, a photograph, and some details in a letter of a singular narrative, to which reference is made in the papers. The details will interest our readers:—

Mr. West, one of the survey party engaged in laying off the Maori reserves at Stewart's Island, gives details of the finding of the skeletons of two human beings. "One

was lying stretched out under an ironwood tree, the bones a little disturbed, a heap of shells at the feet. Close by there were two pairs of Wellington boots, and a pair of low shoes, much worn and cut: the clothes quite rotten. The other lay at a distance of about ten feet in the open, the head down hill, the legs stretched out as if it had rolled away from its fellow. Upon this one were found a Spanish half-dollar piece, a copper coin, and the photograph of a young man smoking a cigar. It is very plain, considering the time that it is supposed to have been exposed to the action of the weather. There must have been other photographs, as there were five small square pieces of glass, and some decaying portions of the frames. There was also an old razor, a bit of red stained glass, and a tooth-brush. Poor fellows, they were not half-a-mile from the Maori settlement! The remains are believed to be those of two men who ran away from an American whaler (name unknown) at Pegasus about nine years ago. A shipmate of theirs, who deserted at the same time, is said by the Maoris to have reached the village in a very exhausted state, with but little clothing left on his person, the rest having been torn off in struggling through the scrub. He stated that he had been forty days coming from Pegasus, during which time he had been living on shell fish, and carrying lighted fern all day, for the purpose of making fires at night."

Some additional confirmatory particulars were subsequently ascertained. The photograph in question was a glass positive, was sent to our correspondent, Mr. Brown, to copy, and copies were, we understand, sent to English illustrated papers, in the hope that they would engrave the portrait and publish the details, and so possibly afford to anxious survivors the mournful satisfaction of knowing the sad fate of the runaways. Speaking of the portrait, Mr. Brown says it was "preserved, and pretty distinct, although it was exposed to the weather for nine years, and the metal preserve was rusted away, only the mat left, and five other glasses, showing that other photographs had been in the possession of the unfortunates, and, owing to some cause or other, were incapable of standing the weather. This photograph which stood so well was unvarnished with either clear or black varnish, simply the collodion film, and this may account for its permanence, for I know of no clear varnish that will stand water for any length of time, and it is well known that black varnish is liable also to crack and fall away, taking the film with it.

"I have read many interesting articles on permanence of photographs, but I am convinced that there could be scarcely anything more permanent than a glass positive photograph unvarnished in any way, and a collodion film alone holding the picture. How would an oil painting itself have stood such a test? The clothes of the unfortunates were all gone, nothing but a few buttons, the skeletons, and a few glasses, and one among them containing a film of collodion with a photograph: the others finished, perhaps, more carefully, varnished, no doubt, and this extra care led to their destruction.

"I have sent photographs and newspapers to the various illustrated papers, and if it is any clue to the identification of the unfortunates, some good will result from my labour of love."

The photograph which, as our correspondent so justly remarks, has proved very satisfactorily permanent, is so little injured that the portraiture would easily be recognized by any one having known the original. It represents a good looking young fellow of apparently from twenty to twenty-five years of age, either clean shaven or beardless, with oval and regular features: the eyes full and well defined; a dark, broad-rimmed felt hat, set slightly on one side, and the style of dress, convey the idea that the wearer was an American. It is a touching souvenir of a sad fate.

Foreign Miscellanea.

M. ALBERT, of Munich, the inventor of Albert type, and Royal Photographer to the Court of Batavia, has just been invested with the Prussian Order of the Crown, of the fourth class, in acknowledgment of the value of his invention.

The members of the Berlin Photographic Society propose to establish a kind of lottery, or, rather, raffle on a large scale, to raise funds for the relief of those who have suffered by the recent war, and invite the co-operation of their brethren. All the more celebrated photographers of Berlin have taken up the matter.

The Photographic Society of Vienna celebrated its tenth anniversary in March last.

M. Brann, of Dornach, has again got his establishment into working order, and although it is believed the change of nationality is somewhat distasteful to the celebrated photographer, no material difference will be made in the working of the establishment. Two sons of M. Brann were in arms during the war, but they have fortunately escaped injury, and are now back again in Alsace.

Some discussion as to the best means of counteracting cyanide of potassium poisoning occurred at a recent meeting of the Berlin Society for the Advancement of Photography. M. Junghans recommended a dilute ammoniac solution, which is either applied to a wound that has been touched with cyanide, or swallowed in cases where the poison has been taken internally; an acidified iron solution, such as is used for developing, is also a good remedy. Dr. Schultz-Sillac thought that a strong dose of alcohol would be a good antidote, as the patient suffers from relaxation of the nerves, and this treatment would have the effect of bracing them up. An incident was mentioned of a man who was wont to use cyanide of potassium for stopping hæmorrhage, and who never felt any subsequent effects of cyanide poisoning from such a course.

M. Ohm, of Hamburg, is said to have invented a new description of sensitive albumenized paper, which will keep good for months. From the fact that fuming with ammonia is necessary before the sheets are placed in the printing frame, the material would appear to be similar to the washed and fumed paper that has recently been brought forward. No practical experience of its qualities has, seemingly, yet been acquired.

M. Kruger has explained the action of the ammonia fuming upon weakly silvered paper to be that of dissolving the albumenate of silver which exists in all albumenized papers, and thus bringing this compound into use in the printing process.

The gold toning salt prepared by M. Pietschmann has been lately reported on, and appears to have given satisfactory results, especially in cold weather, as the solution tones well at a temperature of 10° Cent. Whether its cost is, on the whole, less than that of ordinary gold preparations is a moot point.

A method of purifying—or, rather, improving—old samples of collodion has been proposed by M. Kruger, who suggests the mixing of egg shells, carefully freed from the skin, in any acid samples of the compound. This form of carbonate of lime, which is one of the purest obtainable, has the effect of neutralizing any large amount of acid that may exist, without prejudicing to any degree the particular qualities of the collodion.

M. Grasshoff uses a plate of green glass when reproducing or enlarging negatives, this medium being placed between the original image and the sensitive plate. The green glass is said to soften the glare generated from the transparent portions of the original, and thus allows time for the half tones to be properly developed without over-exposure of the high lights.

Mounting-cards and albums for the Victoria card are being advertised by many of the German houses.

Fritz Luckhardt has lately been giving some attention to the production of cabinet vignette pictures similar to those which have made the name of Reutlinger so famous. The latter gentleman, it is believed, has not yet definitely decided upon his future place of residence.

Adam-Salomon has returned to Paris, but has, of course, been unable as yet to resume work. It is feared that his house—near the Porte Maillot, which escaped the Prussians—has been injured by the recent civil war.

The cameo-vignette portrait is rapidly becoming general in Germany.

A clever specimen of photo-lithography, in the form of a reproduction of a piece of point lace, appears in the *Photographisches Correspondenz* for last month. It is produced by a process of M. J. Schopf, who has enjoyed some experience of methods of this nature.

M. de Constant's article on dry-plate processes, recently published in the *PHOTOGRAPHIC NEWS*, is to appear at full length in some of the German journals.

Dr. August Vogel, one of the professors at the University of Munich, writes a lengthy article upon technical applications of light, in the *Photographisches Archiv*. He enumerates the various artificial lights, and explains the value of spectrum analysis in the examination of luminous rays.

A modification of Lichtdruck has been devised which is adapted to the production of photographs upon porcelain. No practical experience of the process seems yet to have been made known.

The Berlin photographers propose to establish a Mutual Protection Society for the purpose of guarding themselves against the public, who but too frequently obtain specimens and proof-prints without payment. One proposal is to establish an album of defaulters (a species of Black Book), containing portraits of such well known characters as are in the habit of defrauding the photographer. A set of rules has also been drawn up by the Berlin Society, upon which the members are requested to frame their business arrangements.

HYDRATE OF CHLORAL.

A CORRESPONDENT writes as follows:—

PHOTOGRAPHIC NEWS, page 231. Let me notice the proposal, that "a nervous photographer may get a good night's rest by taking a dose of 20 to 50 grains." I have taken this invaluable medicine occasionally for eighteen months; but 10 grains is a sufficient dose, and I have generally found 5 to be enough. If too much is taken, swallow the albumen of an egg. The doses I have known given fill me with astonishment. The best preparation of it, and the pleasantest form of taking it, is "Ferris's syrup of hydro-chloral." As a cough mixture nothing is better than this:—

Oxymel scillæ...	3 drachms
Paregoric (tinct. camph. compos.)	1 drachm
Vin. ipecacuanha	1 "
Potassæ nitr.	30 grains
Acid. citric	10 "
Ferris's hydro-chloral syrup	...	10 "	(one drachm of syrup)
Syrup	1 ounce

A teaspoonful of this three or four times a day, taken as a liquid lozoge, and not gulped. T. F.

MY PORTRAIT.

BY H. R. P.

I HAVE just had my portrait taken. It is the first time in my life that I have submitted to such an operation under professional hands, if I may except two feeble attempts that were made upon me some fifteen years ago, before, therefore, paper positives had become common, and

cartes-de-visite had received the significance they now bear. Of these two pictures, the more striking was executed in a locality still noted for its portraiture—the New Road; and I can yet remember very acutely the flood of bright and vivid light with which I was enveloped and transfixed, while the camera glared at me through its cold glassy eye.

Since then I have never been placed at the mercy of the professional portraitist; and although I have of late gathered some knowledge of photographic matters, and, indeed, pride myself upon being well posted in the more novel methods and manipulations of the art, I have never, all these years, been exposed to the rays of the sun with my head screwed into a rest, or my body in a frame, except within the precincts of my own hot-house. Although portraiture is a particular branch of the art which I have not extensively studied or practised, still the rules and experiences, more perhaps of a theoretical than practical nature, with which I am acquainted have given me considerable confidence as to my capabilities in this direction, had I wished at any time to give vent to my talents. The hints, dodges, and wrinkles that have been placed upon record in the journals during the past few years have not been lost upon me, but have, for the most part, been carefully gathered up in my mind, and incorporated among those well known methodical regulations that govern the conduct of every properly disposed photographer, and from which it is considered by many flat heresy to depart. It is by reason, then, of the somewhat peculiar position in which I find myself that I have determined to give my experiences of a visit that I paid last week to a studio in the vicinity of the Royal Academy.

The photographer to whom I sat has lately achieved some reputation by producing portraits of considerable dimensions, which have been vastly admired for their pictorial effect, and which I will not deny have a certain—well, I can hardly define it; but, at any rate, a certain something which other photographers have not.

Possessed with the idea that *my friends* would be delighted with a large portrait of myself, such as I could hang up in a conspicuous position in my rooms, where they could have no difficulty in seeing it, I determined to pay a visit to my good friend the photographer, from whom, by the way, I hoped that, while I could impart to him, doubtless, some of my superfluous knowledge, I might be able to appropriate quietly a few of the secret dodges by means of which his boasted style of portraiture (which, to tell the truth, is certainly of a totally distinct character to what I sometimes execute) was, no doubt, simply due. As the sequel will show, however, the plan I had contrived was somewhat devoid of success.

As soon as permission was given me to enter the glass room, I repaired up stairs without delay, and found my friend in a corner of his dark closet stealthily engaged with his silver bath. He had begun his tricks already, so I hastily advanced to take note of the proceedings. He tilted the bath slightly with one hand, and with the other drew a piece of paper slowly over the surface of the liquid. By way of explanation he said, "Skim your bath every morning, *if you like*."

I said nothing, but carefully watched his next proceeding. It was to take a large glass plate from the hands of an assistant, and, without scarcely looking at it, much more breathing thereon, to prove its cleanness proceeded to coat it with collodion. I let him go on without hinting a word about his having forgotten to assure himself in this manner of the plate being recently polished; but when, by reason of a want of collodion upon the plate, from careless pouring in the first instance, he proceeded to apply a further quantity from the bottle, I at once pointed out the fatality of such a proceeding. He did not, however, deign to reply, but only poured back the now superfluous liquid into the stock bottle, of which he had a series of three or four to be used in succession.

Finding him somewhat independent on this score, I questioned him about his lenses. I mentioned that Mr. Triplet, the eminent optician, had informed me a lens was being used for these large pictures that it was a positive shame and cruelty to employ, as the field to be covered was far too great for its capacity. "Perhaps," I continued "you stop down well."

"I would not use a lens at all that required a stop." broke in the photographer vehemently. I saw at once it was no good wasting time in discussing a question so obviously indisputable as this, and so gave it up.

As to posing, upon which many people have assured me the main power of this particular photographer rests, I can here, at any rate, make a positive assertion, for, instead of devoting some time and trouble to arranging my body and limbs so as to give me an imposing and dignified appearance, he allowed me to sit pretty well how I chose; and before I could assume that sternness of purpose which I had previously studied, he told me to think through, or go over in my mind, some poem or speech with which I might be acquainted, and forthwith exposed the lens. Nor was this all that was calculated to disturb a well regulated photographic mind, like my own. I observed no less than three gross transgressions of those well-known laws upon which we photographers are wont to base our reputation, and against these I was powerless to protest, even had I possessed the will to do so, for I began to be thoroughly disgusted that a photographer who enjoys such reputation should play pitch and toss with all the valuable experience that the photographic world has taken so long to collect together, and which most of us hold to so dearly and religiously. "Touch the Commons, and down comes the country," says Mr. Spenslow in a beautiful oration, when solemnly summing up the ancient privileges and uses of Doctor's Commons; and so, in like manner, I would ask, what is to become of the prestige of the photographer if you trample upon all our cherished customs and observances?

The errors to which I have alluded may be thus enumerated: The slide was brought from the dark room without envelopment in a cloth, the curtain immediately over the camera being by no means black, although possibly somewhat light-proof; the lens was not capped, but a cloth thrown carelessly over the orifice; finally, just at the moment of exposure, a window admitting diagonal *top* light was opened wide, and the bright rays allowed to shower down over my body, not, however, in any uniform manner, as in the instance of the New Road artist of whom I have spoken, but only partially and in patches.

My patience began to leave me entirely, but I pulled myself together, determined to see the farce to the bitter end. Into the dark room I went, more, perhaps, in sorrow than in anger, for who could not but feel pity for so benighted a brother? Besides, thought I, perhaps the eccentricities are now over, and we shall proceed with more method and observance to rule. Rash hope! The plate was lifted from the slide, and the developer not quietly poured out and gently flowed backwards and forwards, but actually thrown on and off in one single twist, as it were, the plate being afterwards held in a diagonal manner, with scarcely a drop of developer left upon it.

Seeing me closely interested in the operation, my friend said:—

"Well, what do you say, shall I intensify or not?"

I mildly began to state that it certainly was a well known axiom among photographers that pictures, as a rule, stood in need of some intensification, but, from what I had seen, I thought it possible he would be obstinate and independent enough to dispense with the use of a solution altogether. Moreover, while, of course, there were special cases—— But before I had finished the well-merited rebuke, I found my friend had not only opened the door of the dark closet and passed into the

glass room, but, as I live to tell the tale, he actually opened one of the windows, and, leaning out, exposed the unfixed plate to the direct influence of a bright sunshiny morning.

"Now just observe how quickly the film changes colour," said he. I could not reply; my heart was in my mouth; I literally shuddered, and I would willingly have turned away from the horrible sight. It really was too much; the plate rapidly assumed a greenish tint, and if it had been submitted to the light much longer (I think the time was about fifteen seconds), there would, I am sure, have been nothing left of the image.

Dipping in a hyposulphite bath completed the proceedings, in which I should have mentioned my friend seemed to take the greatest delight throughout, as if, indeed, he rather enjoyed this apparently risky and independent mode of working.

By the time we had reached the end of the operation I had ceased to be surprised at anything. Of course, if a man chooses to disregard every well known method and manipulation, and to act in direct defiance to the laws upon which photographic faith is at present built, why we cannot be surprised if he goes rapidly to perdition. If he elects to waste his time and throw away his money in pretending to follow the calling of the orthodox photographer, no positive objection can naturally be made against such a proceeding. But the strangest thing of all is this: that the results he generally produces are (I give my word), on the whole, really exceedingly good in their way; and as not a few of the public are rather taken with the particular way, it follows, of course, that the style is just now a favourite one.

I went down those stairs again with very different notions about photography. As I quietly descended, I began to think that perhaps my friend's mode of working was hardly so absolutely erroneous and bad as one might at first suppose, for, after all, it must be admitted that whether he ought to do so or not, he does succeed to some extent. Whether it would not be better if some of us were just a little more independent in our habits and bolder in our enterprise are matters which would persist in obtruding themselves upon my mind, and I really mean, in future, to consider the matter over seriously. In the meantime, I thought others might not be averse to hearing my first experiences, at any rate for some years, of a professional portraitist, and for this reason I have written out these notes. I ought, perhaps, to mention the fact that the studio in question is situated in one of our largest thoroughfares—Piccadilly, in fact—and that it is at present in the occupation of a gentleman named Blanchard.

PORTRAITS AND PICTURES.

BY JOHANNES GRASSHOFF.*

WHEN in my last paper I expressed a preference for a plainly printed picture over one of a vignetted nature, I did not forget that in the former case a good production necessitates proper attention in matters of detail, such as the correct disposal of the background and properties. These latter are apt to suffer in the picture by reason of the unequal reproduction of the colours presented by the furniture and drapery of the originals. It is not every photographer (especially in the provinces) who can obtain furniture, carpets, and other requisites of the nature most desirable, for one is often greatly mistaken in photographic effect. Even when the purse-strings are sufficiently loosened, it is not easy to overcome a certain amount of prejudice that is apt to exist. In most small towns there is often no suitable workman to be found who is in a position to embody the ideas of the photographer, and it is even difficult to obtain so much as a background or object painted in a proper manner; many photographers

are skilful enough with their retouching brush in correcting defects or making modifications upon the plate, but it is seldom that one finds an operator capable of painting or colouring his own studio paraphernalia.

Another point I would here refer to. In the course of time I have received many communications from all parts of the world, requesting hints and information as regards the illumination of the studio and disposal of the light. There are in existence glass boxes fitted with glass of every variety—white, blue, matt, clear, &c.—so that in some of these hot houses there must be a perfect rainbow of colours; it has struck me with bewonderment very frequently that the production of mediocre pictures even is possible in such localities. In order to reply, to some extent, to these questions, I propose to publish some illustrations of a means of illuminating the model which has in my hands proved the most successful, and believe the method indicated will be found, at any rate to some degree, correct. Of course, when particular effects require to be produced in lighting up the model, the general rules I shall give will not apply to such cases.

One more point connected with the illumination of the studio may be mentioned. If many of the curtains in the glass room are drawn, and the sitter placed close against the window, the contrasts of light and shade are very marked, and are, indeed, frequently of a too glaring nature. If, however, the curtains furthest from the model are partially opened, the gradations from dark to light are softer, and the half tones altogether more delicate, and the Rembrandt effects have not the sharp effect of solar protuberances.

Without reflecting screens it is difficult to work, and, moreover, a shade or cover over the lens is necessary to prevent the action of false light; it is well not to place the camera in invariably the same position and at the same distance, as in many studios it is unfortunately the case, where certain landmarks show the position of the camera. On the contrary, it is better, if the model has taken up a favourable pose, to allow the same to continue, and then, adjusting the inevitable head-rest, to move the apparatus to the spot whence the most successful view is obtained, and to work away from that point. The best pictures which I have produced, or at any rate those which have pleased the most, have nearly all been taken in this manner, at times when I have been compelled to protect my lens with my own body, so that this or that open window should not throw any injurious rays into the lens. Unfortunately, it is very difficult to produce effects of light in pictures of large size, and for this reason we must generally remain contented with photographs of smaller dimensions, such as the cabinet, carte-de visite, or more recent Victoria forms of portrait.

Finally, I would make one or two general remarks upon the subject of "portraits and pictures." This is, indeed, a theme similar to the expression, "genius and talent," for where the one begins there the other leaves off. With the public, as a rule, it is unwise to discuss theories of this kind, for it is often equivalent to saying to the ill-favoured sitter that he only succeeds in imparting ugliness to the apparatus: and this will not, of course, by any means do, as the money question represented by faces of this kind is, as a rule, much more deserving of study than that of those beauties which help so much to dissipate the photographer's gold and silver, but which, nevertheless, must be depicted to supply show cards, to serve as allurements to the public. I, therefore, close this article with the hearty wish that some chemist or other investigator may speedily improve our negative process to such an extent that the colours and tints in nature may be more correctly reproduced, and that one model may not appear of a green and yellow hue, while another is red and brown, for the contrast rendered in our monotone photographs often exceeds that presented by sun freckles or bright brown hair.

THE ALBUMEN PROCESS ON GLASS.

BY M. NOTON.*

In this paper I am supposing you are going to try the albumen process for the first time as a change from some other one you have been working at, and that you have a pretty good idea about apparatus, chemicals, manipulation, exposures, development, and so on. Now the first difference you will find between this and the other one will be that you will probably have to prepare the albumen yourself, as it must be fresh. You can select the source from which you will obtain the raw material; all the other requisites may be bought as usual.

There are three sources from which albumen may be obtained, viz., the eggs of hens, ducks, and turkeys; all are good when fresh. But there are many circumstances affecting the quality of the albumen, independent of time, and to enable anyone to make a thorough scientific inquiry into these circumstances, a well-stocked poultry yard at a farm in the country is needed. Good hen eggs do very well; they should be chosen of a full size, of a regular shape, and not of a fancy breed. Duck albumen is very good; it is of a lighter blue colour than hens', which has a yellow tinge. The few turkey eggs I have used yielded a large quantity of albumen, similar in colour to the hen; it was also very good, but the eggs are not to be obtained so readily as hens' or ducks' eggs are. In Watt's *Dictionary of Chemistry*, at page 65, you will find it stated that "white of egg consists of transparent walled cellulose enclosing an alkaline solution of albuminate of sodium;" and "albumen is insoluble in alcohol and ether."

The albumen must be thoroughly beaten up to a stiff froth. This may be done most effectually by a beater revolving at a great speed. To every fluid ounce of albumen add seven grains of iodide and one and a-half grain of bromide of ammonium, dissolved in one and a-half or two drachms of water, before beating up. Either a few drops of liquor ammonia, or a lump of camphor, or an open bottle with some carbolic acid in it, may be enclosed amongst the froth; then afterwards covered up and put aside in a cool place to settle down again into a liquid, arranging so that it may have at least twelve hours to do so.

For printing transparencies the bromide may be left out of the albumen, as you have only one colour in the negative to consider. The bromide may be of use for landscape photography.

Early in the last month I made the following experiment:—Ten grains of bromide of ammonium were dissolved in one ounce of albumen. A plate was coated, dried, dipped in the aceto-nitrate bath, washed, covered with solution of hypo, washed, and dried, the result being that a stranger would take the plate to be ground glass, very fine on one side, but there is this difference—when held up to a small bright light there is a circle of prismatic colours; also, in using it in the camera as a focussing surface (for which it does very well), you see the colours, so that there is a suspicion that the bromide may interfere a little with the sharpness of albumen transparencies. In former times bromide was not used in the original process.

When the albumen is about to be used, it should be filtered through fine calico, two hours or so beforehand, into a distributor.

The next item we come to is the nitrate of silver bath. The strength of the nitrate of silver solution for sensitizing the albumenized plates had better be started with as low as possible—say fifty or sixty grains to the ounce of water. Saturate one third or fourth part of the bulk with iodide of silver; settle and decant, or filter into the other two-thirds or three-fourths; make the solution slightly acid with glacial acetic acid. There is no necessity for using such large quantities of acid as were prescribed in times past.

Do not use a bath soon after it is made or considerably strengthened, but let it stand a day or so. Filter just before use.

One very important element is pure water for making the various solutions required, and giving a final wash. You should be able to condense the water yourself, making a sufficient quantity to last some months, stored up in glass bottles.

It will save you much trouble and annoyance if you have good glass plates. For negatives intended to be used for printing transparencies by contact, patent plate should be used. Large negatives, intended to be reduced in the camera, may be of other good glass. Grind the edges on a flat stone; then clean them all over. If the glasses are not patent plate, try each surface with a knife to find the worst side; having satisfied yourself on this point, mark that side with a diamond at one corner. You see, patent plate needs no examination with a knife, and both sides are usable, consequently it is the best in the end, and may be more readily and perfectly coated with albumen. When plates are too large to be grasped by the hand a little more inconvenience arises, but it is soon got over.

The actual preparation of an albumen plate is really a very easy thing to do when you have all the requisite tackle and material ready and in proper condition, and a suitable place to work in. I say when you have all things right, &c., for on this hang all the troubles and difficulties of the process, especially in reference to the liability to have bubbles or fibres in the film.

Microscopically-fine bubbles of air will be diffused through the albumen, after filtration sometimes, if you do not mind, and this is the way they are produced:—Occasionally the settled-down albumen is thinner, and passes through the cloth filter into the distributor quicker, drawing down air by the side of the filter-point along with it to the end of the glass funnel. This is a bothering circumstance, but I do not think it is a worse one than when the albumen is so thick that it will scarcely go through the filter at all. The only remedy for this state of things is to keep drawing off portions of the albumen and returning them into the filter above, till the cloth gets partly silted up, and the liquid goes through slower; then, when all has passed through, let it stand quietly for two or three hours, so that any bubbles present may rise to the surface. It is rather remarkable that the act of beating up the albumen into a stiff froth saturates it with millions of bubbles, and these leave the liquid so free in time that it may, with care, be put on to a glass plate, as was originally given, without filtration. I have myself frequently decanted the albumen into the distributor direct when I have wanted to try a plate hastily. Filtration is an insurance against any solid bits of material suspended accidentally in the liquid.

There are two ways of coating a glass plate with albumen. The first is—After pouring off the excess, putting the plate away somewhere, quite level, till it dries. The other way is by whirling after pouring off, and drying at once on a level hot-water plate. In putting the albumen upon the plate you have here another risk of bubbles, which may undo all at the last step.

Albumen differs from collodion considerably in being a watery liquid, and, as like takes to like, the surface of the glass plate must be chemically damp, which will cause the albumen to flow quite as readily as collodion does on a dry plate, and attach itself to the surface without rolling over and enclosing small bubbles of air, the principal cause of the black spots I have frequently heard complained of. Do not put the poured-off albumen into the filtering funnel, but into the beating-up jar or jug. Always have a good stock in the distributor to begin with. As regards fibres and dust, they mean a dry atmosphere, which you had better avoid.

When the film is dry, and the glass still slightly warm, it is to be immersed in the nitrate of silver bath for about forty to sixty seconds with motion, taken out, drained,

dipped in a bath of water, taken out, and put into a second one, or tray, so that it can be rocked, then into a tray of a weak (say ten to fifteen grains) solution of muriate of ammonia, taken out, swilled with water from a jug, and whirled. It is now ready to receive a second coat of albumen. This being applied, the excess poured off, whirled, and dried, the plate may be stored away ready for sensitizing afterwards as wanted, which must, after the above, be done in the dark room. If the plates are for early use, the bath of muriate of ammonia may be left out, using a little more water.

Before sensitizing for the second time the plate must be slightly warmed as before. Let it go through the first and second water baths, whirl, then cover the surface with solution of gallic acid, pour off, and whirl rapidly; put away to complete the drying without heat. The plate should have not less than twelve hours' rest before exposure.

Albumen plates have a character for being slow. They are considered slow because it takes a long time to develop the picture; this will depend upon the means used to do it. The imperviousness of the coagulated film of albumen has to be considered.

If you put a plate into simple water with the intention of softening the film, so that you can clean it off, you will find it resist for a considerable time; but if you use a strong solution of soda, the removal may be much quicker done, as the alkali softens the film, causing it to be more penetrable. Now, this has only to be done in moderation in development, and the time will be reduced. It is a practice with me to use gallic acid with a trace of nitrate of silver.

Using pure water in the solutions, you may let the development go on all night in the dark, covered up, when generally the picture is ready for completion in the morning; or you may cover the plate with gallic acid without silver, and afterwards go on with strengthening the details at your leisure. Alkaline development may be employed to bring out the picture. The first simple step is to use gallic acid with a drop or two of carbonate of soda or ammonia; gallic acid and acetate of lead; pyrogallic acid, plain or alkaline, may be used.

There are several formulæ and instructions on development in the journals and almanacs, to which I must refer you; only reminding you that you had better destroy the alkalinity of the developed picture before fixing, or blisters and mination will be the result. Solution of hyposulphite of soda, made slightly milky with acid, to be used for fixing. Wash, whirl, and dry.

TO TINT PHOTOGRAPHS SLIGHTLY.

The following easy method for tinting photographs is well adapted for persons who have little leisure for the other and more artistic manner.

Having prepared the photograph in the usual way, take a little pink madder or carmine, and lay it on the cheek with a clean pencil. Soften it carefully all round the edges, blending the tint into the face. Repeat the process once and again, until you have obtained nearly as much colour as necessary; I say nearly as much, because you have to pass the general flesh wash over it, which has the effect of darkening it considerably. For the purpose of softening, it will be as well to have two pencils on one holder. It might appear that putting on the colour of the cheek at once, and softening it, would suffice; but you will get it far softer by doing it with a very pale tint two or three times, than you possibly can by making it at once as powerful as necessary; besides, it is impossible to soften a strong colour so well as a pale tint. When the colour is quite dry, go over the whole of the face with the flesh tint, then put in the hair, eyes, eyebrows, and lips; round off the forehead with grey, and apply the same to those parts of the face where you observe it to be in nature. If your photograph be a very dark one, you will not require so much grey in it as if it were a light

impression. Next wash in the background, and proceed with the draperies, &c.

Return now to the face: strengthen the carnations, greys, and shadows, by hatching delicate tints over them; put the light in the eyes, and the spirited touches about it, and the eyebrows, mouth, &c., and bluish off the hair. In dark photographs, you will require to lay the lights on the hair with body colour, as it is generally much darker than it appears in nature. Make out the linen with a grey, deepening it in the darkest parts, and lay on the high lights with constant or Chinese white. Proceed next to shadow the drapery, and when you have obtained the required depth, scumble in the high lights, using a bare pencil and a very gentle hand, as before directed. Give the background another wash, if requisite, and your photograph is finished; or make up a tint of orange vermilion and white, according to the complexion, and lay it smoothly over the face and hands; then put on the carnations with rose madder, and shadow up the face with orange tint, and proceed as above to finish. If the backgrounds and draperies appear dead, you may take a piece of very soft washing silk and rub them up a little, which will have the same effect as if they had been hot pressed. Whenever body colour has been used, the rubbing will be ineffective. Neither rubbing nor hot pressing will give a shine to any but transparent tints. If there be metal buttons, chains or epulettes, they must be laid over the dress with body colours; a very good ground for them is red chrome and gamboge shadowed with burnt umber, and heightened on the lights with lemon chrome and Chinese white. By the foregoing methods it will be unnecessary to hatch or stipple a great deal; for you will find that the face will come out very soft and round without it, but the effect is far inferior to that produced by the other process.—*Photographer's Friend.*

ON PHOTOGRAPHY IN THE PRINTING PRESS: BEING A DESCRIPTION OF THE WORKING OF THE HELIOTYPE PROCESS.

BY ERNEST EDWARDS, ESQ., B.A. (CANTAB).*

DISCUSSION.

Mr. GEORGE WALLIS said he must congratulate Mr. Edwards not only on the character of his invention, but also on that of his paper, in which he had given so lucid an explanation of the process of which he was the inventor. It often happened that when papers were read, in which, as in his own case, appeared great promise for the future, subsequent events showed that the inventor had calculated on the public help more than he had a right to do; and he could therefore heartily sympathise with the lecturer when he said that this was a process in which new materials, new methods, and new skill had to be employed. It was on account of these things that many new and useful processes hung fire, and were not carried out. He had generally found that those he employed to carry out any particular part of a process knew much better than he did what he wanted. The result was, that you always had a great deal to get out of people's heads before you could get what you wanted into them. There were three points in this invention which appeared to him of great importance: First, the ingenious method of using a mask for the purpose of keeping a clean margin to the paper, thus avoiding the expense and trouble of mounting, which was a matter of great importance in book illustrations, for those who had bought books illustrated with mounted photographs generally found that a trouble arose from the curling of the film on which the subject was printed. The second point was, the ingenious and artistic process of employing two or three gradations of ink, that of a stiff character in the first instance, and thinner ink afterwards, by which the picture was built up, and produced in a manner which no single ink could ever obtain. Finally—and this was of immense importance in the economy of the invention—the film itself, after having been used for as many copies as were required at the time, could be put aside and brought out again, whenever necessary. In the case of lithography, if you wished to produce a second edition

of impressions, it was necessary either to pay for re-drawing on the stone, or to pay a rental for keeping the original picture upon the stone; but in this case the gelatine was, by the process itself, really converted into leather, and, therefore, being equally durable, there was no reason why the printing surface should not be kept as long as was required.

Dr. RYLEY said no process was perfect at first, and from what he had seen of the beautiful one before them—for up to the present time nothing had been produced at all equal to it—it appeared to him that there was a kind of water-mark on the paper, which he had particularly noticed in one print called "The Kind Sister." He should like to know, having paid particular attention to photography, what was the cause of these faults, for faults they undoubtedly were. It occurred to him they might be caused by the whole of the water not being squeezed out in the course of printing.

Mr. SADDLER asked how long the film took to dry.

Mr. EDWARDS said from twenty-four to thirty-six hours, at a temperature of 90°.

Mr. SADDLER said he had noticed in all the impressions more or less evidence of that which he supposed attached to the gelatine process of drying. This was one of the fatal objections to the Pletsch and Dallas processes, which required forty-eight hours to dry the film. When it afterwards came to be moulded in gutta-percha, every particle of dust was moulded also, and in the transfer to the copper-plate this was again repeated in little specula of copper, which stood up, and had to be scraped off the lines afterwards brought out by a graver.

Mr. SPILLER, as a photographer of long standing, desired to offer his congratulations on the very beautiful process which Mr. Edwards had succeeded in perfecting. He had watched the various methods which had been brought out for mechanical printing, but certainly, until the last year or eighteen months, with the exception of the Woodburytype, which Mr. Edwards had referred to, there seemed no prospect of substantial success, until the appearance of the Albert-type, by which most glorious specimens of art were certainly produced; and every one must have admired the magnificent specimens sent to this country. At the present moment, however, the public were in ignorance of the precise details of that process, and he believed Mr. Edwards was the first to give a connected account of the operation. With regard to the water-marks which had been spoken of, he must say that, although he had noticed this on some of the early carbon prints, there was, in the specimens of Mr. Edwards's printing which he had seen, great whiteness and brilliancy in the high lights. With regard to the dust attaching to the film in the process of drying, that could easily be got over by employing a desiccating process, by which the gelatine might be dried without contact with the external air. He should like to ask what was the minimum of copies required in order to enable the process to successfully compete with the ordinary method of silver printing. For instance, in the event of 250 copies being required, would it be found more economical?

Mr. SUAREZ inquired what would be the absolute cost of printing 500 copies. He had recently had to pay £12 for such a number of photographic prints, including mounting, and he certainly should have preferred the present process, one great advantage in it being that all the copies were absolutely alike, which was never the case in photographs, which varied greatly; and in the second place the curling and crinkling, which had been already referred to, was entirely avoided.

Mr. YAPP said some months ago he had the pleasure of exhibiting a few specimens of this process to two gentlemen in Paris—M. Lemercier and M. Rosa—who were very much pleased with them. M. Rosa afterwards took him into his press-room, and said: "I have brought this gentleman to introduce him to you; he has brought to France specimens of a process which is about to ruin us all. We are only able to work with a lithographic press, but he is going to put it on the steam press." That was going a little beyond what he had stated, but he did not despair of the time coming when Mr. Edwards would be able to fulfil these words. He was quite certain that when poor, unfortunate Paris was again in a position to do anything in the way of art, this process, or something analogous to it, would find great favour.

Mr. BEDFORD asked whether the paper was damped, as in ordinary lithographic and letter-press printing. He said it seemed an admirable process for reproducing fac-simile works of art, such as those in Turner's "Liber Studiorum."

* Continued from p. 237.

Mr. BAILEY asked if this process had ever been applied to glass or china, by using oxides instead of ink.

Mr. EDWARDS said they had produced prints on paper with a suitable ink, mixed up with oxides, specially for the transfer to pottery, but they had not yet had time to carry it further.

Mr. BAILEY said something similar had been attempted a few years ago by Mr. Jubert, but there were so many failures that it had to be abandoned.

Mr. FITZCOCK said this process would undoubtedly be a very great boon to artists, because they could get every touch of their work reproduced in a manner which no other process could imitate. Photolithography has lately been creeping much into use, and this process would no doubt be of great assistance in giving a transfer, which might be placed upon stone and afterwards printed by steam, which was not possible by any other way.

Mr. TICKNELL asked whether the process was adapted to transferring to glass, so as to produce transparent pictures for ornamental windows in galleries, staircases, &c.

Mr. EDWARDS, in reply to the observations which had been made, said the dust on the surface of the films had been, to a great extent, disposed of by Mr. Spiller. He suggested that it was owing to its being a new process, working with new appliances and new hands, which occasioned the water-marks. Really, a great difficulty to contend with was in getting a suitable kind of paper. Messrs. De La Rue had recently made some admirable paper for the purpose, but they had not elsewhere been able to obtain any on which they could rely, one sample being very good, but a second quantity proving quite the reverse. He was now referring to papers with a slight surface upon them, because such papers better produced the effect of photographic printing; when he found it impossible to get a reliable paper of that character, he fell back on ordinary plate paper, which, for many subjects, gave quite as good results—indeed, in some respects, far better; it did not, however, answer so well when it was required to imitate the effect of photography, one difficulty being that the pressure had to be kept on the plate for some little time, and if the printer was not careful to damp the plate properly, the continued pressure made the plate go into lumps, which occasioned the water-marks. This, however, was a technical difficulty, which was disappearing day by day. The dust could, of course, be completely got rid of, as indicated by Mr. Spiller, but he did not think the appearance spoken of was due entirely to that cause. The dust did not act in the same way as in the copper-plate that had been referred to, for dust was practically transparent, so that the light acted through it. If, however, spots did arise from such a cause, there was another remedy, viz., to use the under surface of the film, where there could be no dust, to print from. The cost, as compared with silver printing, was a difficult matter to enter upon, but he might say that, for one or two impressions only, it would not be worth while to prepare and make ready, as it was termed, the printing surface. For large-sized pictures, however, they could compete with the silver process, even for six impressions. In such cases the cost would be about 1s. per foot. Book illustrations, of size, could be supplied ready for the binder at 1½d. each; smaller sizes would cost more comparatively speaking, because the labour would be almost as great; but larger sizes less, in proportion. They were at present a long way from steam printing, but he believed that time would come, for the inking of the plates was so purely a mechanical operation that he saw no insuperable difficulty in the way. The plate seemed to discriminate for itself how much ink was required, and when the proper quantity was supplied, no additional amount of rolling would add to it. He was, at the present time, engaged in experiments with a view to putting these films into a lithographic machine. This was the first step towards steam printing, and he anticipated no difficulty with regard to the inking part of the process. The paper was used dry, just as it was supplied. Turner's "Liber Studiorum" was a magnificent subject for the process, and it was in contemplation to publish a complete facsimile edition of the whole series, under the auspices of a very distinguished author. As to transferring the impressions to glass, pottery, &c., he might remark that it was quite different from any photo-enamelling process, in which the colour was printed directly on the surface of the glass or china. The impression was printed on this tissue paper in the proper colours, the paper being then handed to the manufacturer to be used in the ordinary way. In fact, a picture was produced in the same material as in the methods ordinarily used, but by photographic means. The

transfer to stone was similar. He had specimens printed from the stone which had been produced from impressions taken in transfer ink and then laid down in the ordinary way; but this was only suitable to drawings in which the effect was produced by lines and dots.
